

Chapter : 20. STRAIGHT LINES

Exercise : 20A

Question: 1

Find the distance

Solution:

(i) Formula Used:

$$\text{Distance between any two points } A(x_1, y_1) \text{ and } B(x_2, y_2) = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

$$\text{Distance between } A(2, -3) \text{ and } B(-6, 3) = \sqrt{(-6 - 2)^2 + (3 - (-3))^2}$$

$$= \sqrt{64 + 36} = \sqrt{100}$$

$$= 10 \text{ units}$$

Therefore, the distance between points A and B is 10 units.

$$(ii) \text{ Distance between } C(-1, -1) \text{ and } D(8, 11) = \sqrt{(8 - (-1))^2 + (11 - (-1))^2}$$

$$= \sqrt{81 + 144} = \sqrt{225}$$

$$= 15 \text{ units}$$

Therefore, the distance between points C and D is 10 units.

$$(iii) \text{ Distance between } P(-8, -3) \text{ and } Q(-2, -5) = \sqrt{(-2 - (-8))^2 + (-5 - (-3))^2}$$

$$= \sqrt{36 + 4} = \sqrt{40}$$

$$= 2\sqrt{10} \text{ units}$$

Therefore, the distance between the points P and Q is $2\sqrt{10}$ units.

$$(iv) \text{ Distance between } R(a + b, a - b) \text{ and } S(a - b, a + b) =$$

$$\sqrt{((a - b) - (a + b))^2 + ((a + b) - (a - b))^2}$$

$$= \sqrt{4b^2 + 4b^2}$$

$$= 2b\sqrt{2} \text{ units}$$

Therefore, the distance between the points R and S is $2b\sqrt{2}$ units.

Question: 2

Find the distance

Solution:

$$\text{Distance of point } P(6, -6) \text{ from origin } (0, 0) = \sqrt{(0 + 6)^2 + (0 - 6)^2}$$

$$= \sqrt{36 + 36}$$

$$= 6\sqrt{2} \text{ units}$$

Therefore, the distance of the point P from the origin is $6\sqrt{2}$ units.

Question: 3

If a point P(x, y)

Solution:

Given: Point P(x, y) is equidistant from points A(6, -1) and B(2, 3)

i.e., distance of P from A = distance of P from B

$$\Rightarrow \sqrt{(x - 6)^2 + (y + 1)^2} = \sqrt{(x - 2)^2 + (y - 3)^2}$$

Squaring both sides,

$$\Rightarrow (x - 6)^2 + (y - 1)^2 = (x - 2)^2 + (y - 3)^2$$

$$\Rightarrow x^2 - 12x + 36 + y^2 - 2y + 1 = x^2 - 4x + 4 + y^2 - 6y + 9$$

$$\Rightarrow -12x + 36 + 2y + 1 = -4x + 4 - 6y + 9$$

$$\Rightarrow -8x + 8y = -24$$

$$\Rightarrow x - y = 3$$

Therefore, $x - y = 3$ is the required relation.

Question: 4

Find a point on t

Solution:

Let the point on x-axis be P(x, 0).

Given: Point P(x, 0) is equidistant from points A(7, 6) and B(-3, 4)

i.e., distance of P from A = distance of P from B

$$\Rightarrow \sqrt{(x - 7)^2 + 36} = \sqrt{(x + 3)^2 + 16}$$

Squaring both sides,

$$\Rightarrow (x - 7)^2 + 36 = (x + 3)^2 + 16$$

$$\Rightarrow x^2 - 14x + 49 + 36 = x^2 + 6x + 9 + 16$$

$$\Rightarrow -20x = -60$$

$$\Rightarrow x = 3$$

Therefore, the point on the x-axis is (3, 0).

Question: 5

Find the distance

Solution:

(i) Given: AB is parallel to the x-axis.

When AB is parallel to the x-axis, the y co-ordinate of A and B will be the same.

$$\text{i.e., } y_1 = y_2$$

$$\text{Distance} = \sqrt{(x_2 - x_1)^2 + (y_1 - y_1)^2}$$

$$\Rightarrow |x_2 - x_1|$$

Therefore the distance between A and B when AB is parallel to x-axis is $|x_2 - x_1|$

(ii) Given: AB is parallel to the y-axis.

When AB is parallel to the y-axis, the x co-ordinate of A and B will be the same.

$$\text{i.e., } x_2 = x_1$$

$$\text{Distance} = \sqrt{(x_1 - x_1)^2 + (y_2 - y_1)^2}$$

$$\Rightarrow |y_2 - y_1|$$

Therefore the distance between A and B when AB is parallel to y-axis is $|y_2 - y_1|$

Question: 6

A is a point on t

Solution:

Given: The two points are A(-8, 0) and B(0, 15)

$$\text{Distance between A and B} = \sqrt{(0 + 8)^2 + (15 - 0)^2}$$

$$\Rightarrow \sqrt{64 + 225}$$

$$= \sqrt{289}$$

$$= 17 \text{ units}$$

Therefore, the distance between A and B is 17 units.

Question: 7

Find a point on t

Solution:

Let the point on the y-axis be P(0, y)

Given: P is equidistant from A(-4, 3) and B(5, 2).

$$\text{i.e., } PA = PB$$

$$\Rightarrow \sqrt{(-4 - 0)^2 + (3 - y)^2} = \sqrt{(5 - 0)^2 + (2 - y)^2}$$

Squaring both sides, we get

$$\Rightarrow (-4 - 0)^2 + (3 - y)^2 = (5 - 0)^2 + (2 - y)^2$$

$$\Rightarrow 16 + 9 - 6y + y^2 = 25 + 4 - 4y + y^2$$

$$\Rightarrow 25 - 6y = 29 - 4y$$

$$\Rightarrow 2y = -4$$

$$\Rightarrow y = -2$$

Therefore, the required point on the y-axis is (0, -2).

Question: 8

Using the distance

Solution:

Given: The 3 points are A(3, -2), B(5, 2) and C(8, 8).

$$AB = \sqrt{(5 - 3)^2 + (2 + 2)^2}$$

$$= \sqrt{4 + 16}$$

$$= 2\sqrt{5} \text{ units} \dots\dots(1)$$

$$BC = \sqrt{(8 - 5)^2 + (8 - 2)^2}$$

$$= \sqrt{9 + 36}$$

$$= 3\sqrt{5} \text{ units} \dots\dots(2)$$

$$AC = \sqrt{(8 - 3)^2 + (8 + 2)^2}$$

$$= \sqrt{25 + 100}$$

$$= 5\sqrt{5} \text{ units(3)}$$

From equations 1, 2 and 3, we have

$$\Rightarrow AC = AB + BC$$

This is possible only if the points are collinear.

Therefore, the points A, B and C are collinear.

Hence, proved.

Question: 9

Show that the poi

Solution:

Given: The 3 points are A(7, 10), B(-2, 5) and C(3, -4)

$$AB = \sqrt{(-2 - 7)^2 + (5 - 10)^2}$$

$$= \sqrt{81 + 25}$$

$$= \sqrt{106} \text{ units(1)}$$

$$BC = \sqrt{(3 + 2)^2 + (-4 - 5)^2}$$

$$= \sqrt{25 + 81}$$

$$= \sqrt{106} \text{ units(2)}$$

$$AC = \sqrt{(3 - 7)^2 + (-4 - 10)^2}$$

$$= \sqrt{16 + 196}$$

$$= \sqrt{212} \text{ units}$$

From equations 1 and 2, we have

$$\Rightarrow AB = BC$$

Therefore, ΔABC is an isosceles triangle(3)

$$\text{Also, } AB^2 = 106 \text{ units(4)}$$

$$BC^2 = 106 \text{ units(5)}$$

$$AC^2 = 212 \text{ units(6)}$$

From equations 4, 5 and 6, we have

$$AB^2 + BC^2 = AC^2$$

So, it satisfies the Pythagoras theorem.

ΔABC is right angled triangle(7)

From 3 and 7, we have

ΔABC is an isosceles right angled triangle.

Hence, proved.

Question: 10

Show that the poi

Solution:

Given: The 3 points are A(1, 1), B(-1, -1) and C(- $\sqrt{3}$, $\sqrt{3}$).

$$AB = \sqrt{(-1 - 1)^2 + (-1 - 1)^2}$$

$$= \sqrt{4 + 4}$$

$$= 2\sqrt{2} \text{ units} \dots\dots(1)$$

$$BC = \sqrt{(-\sqrt{3} + 1)^2 + (\sqrt{3} + 1)^2}$$

$$= \sqrt{3 - 2\sqrt{3} + 1 + 3 + 2\sqrt{3} + 1}$$

$$= 2\sqrt{2} \text{ units} \dots\dots(2)$$

$$AC = \sqrt{(-\sqrt{3} - 1)^2 + (\sqrt{3} - 1)^2}$$

$$= \sqrt{3 + 2\sqrt{3} + 1 + 3 - 2\sqrt{3} + 1}$$

$$= 2\sqrt{2} \text{ units} \dots\dots(3)$$

From equations 1, 2 and 3, we have

$$AB = BC = AC = 2\sqrt{2} \text{ units.}$$

Therefore, ΔABC is an equilateral triangle each of whose sides is $2\sqrt{2}$ units.

Hence, proved.

Question: 11

Show that the poi

Solution:

Given: The 4 points are A(2, -2), B(8, 4), C(5, 7) and D(-1, 1).

Note: For a quadrilateral to be a rectangle, the opposite sides of the quadrilateral must be equal and the diagonals must be equal as well.

$$AB = \sqrt{36 + 36}$$

$$= 6\sqrt{2} \text{ units} \dots\dots(1)$$

$$BC = \sqrt{9 + 9}$$

$$= 3\sqrt{2} \text{ units} \dots\dots(2)$$

$$CD = \sqrt{36 + 36}$$

$$= 6\sqrt{2} \text{ units} \dots\dots(3)$$

$$AD = \sqrt{9 + 9}$$

$$= 3\sqrt{2} \text{ units} \dots\dots(4)$$

From equations 1, 2, 3 and 4, we have

$$AB = CD \text{ and } BC = AD \dots\dots(5)$$

$$\text{Also, } AC = \sqrt{9 + 81}$$

$$= 3\sqrt{10} \text{ units}$$

$$BD = \sqrt{81 + 9}$$

$$= 3\sqrt{10} \text{ units}$$

$$\text{Thus, } AC = BD \dots\dots(6)$$

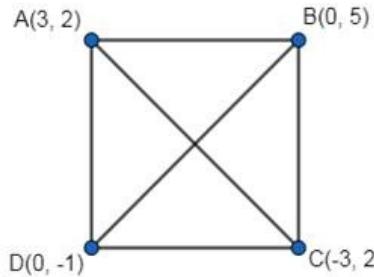

From equations 5 and 6, we can conclude that the opposite sides of quadrilateral ABCD are equal and the diagonals of ABCD are equal as well.

Therefore, point A, B, C and D are the angular points of a rectangle.

Question: 12

Show that A(3, 2)

Solution:

Given: The points are A(3, 2), B(0, 5), C(-3, 2) and D(0, -1).

Note: For a quadrilateral to be a square, all the sides of the quadrilateral must be equal in length and the diagonals must be equal in length as well.

$$AB = \sqrt{(0 - 3)^2 + (5 - 2)^2} = \sqrt{9 + 9}$$

$$= 3\sqrt{2} \text{ units}$$

$$BC = \sqrt{(-3 - 0)^2 + (2 - 5)^2} = \sqrt{9 + 9}$$

$$= 3\sqrt{2} \text{ units}$$

$$CD = \sqrt{(0 + 3)^2 + (-1 - 2)^2} = \sqrt{9 + 9}$$

$$= 3\sqrt{2} \text{ units}$$

$$DA = \sqrt{(3 - 0)^2 + (2 + 1)^2} = \sqrt{9 + 9}$$

$$= 3\sqrt{2} \text{ units}$$

Therefore, AB = BC = CD = DA(1)

$$AC = \sqrt{(-3 - 3)^2 + (2 - 2)^2}$$

$$= 6 \text{ units}$$

$$BD = \sqrt{(0 - 0)^2 + (-1 - 5)^2}$$

$$= 6 \text{ units}$$

Therefore, AC = BD(2)

From 1 and 2, we have all the sides of ABCD are equal and the diagonals are equal in length as well.

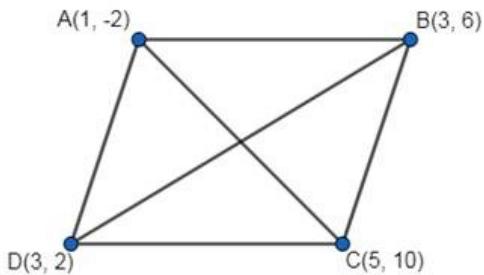

Therefore, ABCD is a square.

Hence, the points A, B, C and D are the vertices of a square.

Question: 13

Show that A(1, -2)

Solution:

Given: Vertices of the quadrilateral are A(1, -2), B(3, 6), C(5, 10) and D(3, 2).

Note: For a quadrilateral to be a parallelogram opposite sides of the quadrilateral must be equal in length, and the diagonals must not be equal.

$$AB = \sqrt{(3 - 1)^2 + (6 + 2)^2} = \sqrt{4 + 64}$$

$$= 2\sqrt{17} \text{ units}$$

$$BC = \sqrt{(5 - 3)^2 + (10 - 6)^2} = \sqrt{4 + 16}$$

$$= 2\sqrt{5} \text{ units}$$

$$CD = \sqrt{(3 - 5)^2 + (2 - 10)^2} = \sqrt{4 + 64}$$

$$= 2\sqrt{17} \text{ units}$$

$$DA = \sqrt{(1 - 3)^2 + (-2 - 2)^2} = \sqrt{4 + 16}$$

$$= 2\sqrt{5} \text{ units}$$

Therefore, AB = CD and BC = DA(1)

$$AC = \sqrt{(5 - 1)^2 + (10 + 2)^2} = \sqrt{16 + 144}$$

$$= 4\sqrt{10} \text{ units}$$

$$BD = \sqrt{(3 - 3)^2 + (2 - 6)^2}$$

$$= 4 \text{ units}$$

Therefore, AC ≠ BD(2)

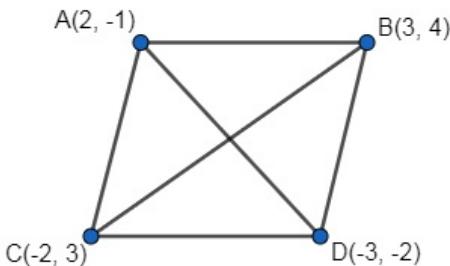

From 1 and 2, we have

Opposite sides of ABCD are equal, and diagonals are not equal. Hence, points A, B, C and D are the vertices of a parallelogram.

Question: 14

Show that the poi

Solution:

Given: Vertices of the quadrilateral are A(2, -1), B(3, 4), C(-2, 3) and D(-3, -2).

Note: For a quadrilateral to be a rhombus, all the sides must be equal in length and the diagonals must not be equal.

$$AB = \sqrt{(3 - 2)^2 + (4 + 1)^2} = \sqrt{1 + 25}$$

= $\sqrt{26}$ units

$$BC = \sqrt{(-2 - 3)^2 + (3 - 4)^2} = \sqrt{25 + 1}$$

= $\sqrt{26}$ units

$$CD = \sqrt{(-3 + 2)^2 + (-2 - 3)^2} = \sqrt{1 + 25}$$

= $\sqrt{26}$ units

$$DA = \sqrt{(2 + 3)^2 + (-1 + 2)^2} = \sqrt{25 + 1}$$

= $\sqrt{26}$ units

Therefore, $AB = BC = CD = DA \dots\dots(1)$

$$AC = \sqrt{(-2 - 2)^2 + (3 + 1)^2} = \sqrt{16 + 16}$$

= $4\sqrt{2}$ units

$$BD = \sqrt{(-3 - 3)^2 + (-2 - 4)^2} = \sqrt{36 + 36}$$

= $6\sqrt{2}$ units

Also, $AC \neq BD \dots\dots(2)$

From 1 and 2, we have all the sides are equal and diagonals are not equal.

Hence, the points A, B, C and D are the vertices of a rhombus.

Question: 15

If the points A (

Solution:

Given: Vertices of the parallelogram are A(-2, -1), B(1, 0), C(x, 3) and D(1, y).

To find: values of x and y.

Since, ABCD is a parallelogram, we have $AB = CD$ and $BC = DA$.

$$AB = \sqrt{(1 + 2)^2 + (0 + 1)^2} = \sqrt{9 + 1}$$

= $\sqrt{10}$ units

$$BC = \sqrt{(x - 1)^2 + 9}$$

$$CD = \sqrt{(1 - x)^2 + (y - 3)^2}$$

$$DA = \sqrt{9 + (1 + y)^2}$$

Since $AB = CD$,

$$\Rightarrow \sqrt{10} = \sqrt{(1 - x)^2 + (y - 3)^2}$$

Squaring both sides, we get

$$\Rightarrow 10 = (1 - x)^2 + (y - 3)^2$$

$$\Rightarrow 10 = 1 - 2x + x^2 + y^2 - 6y + 9$$

$$\Rightarrow x^2 + y^2 - 2x - 6y = 0 \dots\dots(1)$$

Since $BC = DA$,

$$\Rightarrow \sqrt{(x - 1)^2 + 9} = \sqrt{9 + (1 + y)^2}$$

Squaring both sides,

$$\Rightarrow (x - 1)^2 + 9 = 9 + (1 + y)^2$$

$$\Rightarrow x^2 - 2x + 1 = 1 + 2y + y^2$$

$$\Rightarrow x^2 - y^2 - 2x - 2y = 0 \dots\dots(2)$$

Equation 1 - Equation 2 gives us,

$$\Rightarrow 2y^2 - 4y = 0$$

$$\Rightarrow y^2 - 2y = 0$$

$$\Rightarrow y(y - 2) = 0$$

$$\Rightarrow y = 0 \text{ or } y = 2$$

But $y \neq 0$ because then point D(1, 0) is same as B(1, 0)

Therefore, $y = 2$

When $y = 2$, from equation 1,

$$\Rightarrow x^2 + 4 - 2x - 12 = 0$$

$$\Rightarrow x^2 - 2x - 8 = 0$$

$$\Rightarrow (x - 4) \times (x + 2) = 0$$

$$\Rightarrow x = 4 \text{ or } x = -2$$

So, the possible set of values for x and y are:

$$x = 4, y = 2$$

$$x = -2, y = 2$$

But when $x = -2$, then C(-2, 3). Then ABCD does not form a parallelogram.

Therefore, the only solution is $x = 4$ and $y = 2$.

Question: 16

Find the area of

Solution:

Given: The vertices of the triangle are A(-3, -5), B(5, 2) and C(-9, -3).

Formula: Area of $\Delta ABC = \frac{1}{2} [x_1(y_2 - y_3) + x_2(y_3 - y_1) + x_3(y_1 - y_2)]$

Here,

$$x_1 = -3, y_1 = -5$$

$$x_2 = 5, y_2 = 2$$

$$x_3 = -9, y_3 = -3$$

Putting the values,

$$\text{Area of } \Delta ABC = \frac{1}{2} [-3(2 + 3) + 5(-3 + 5) - 9(-5 - 2)]$$

$$= \frac{1}{2} [-15 + 10 + 63]$$

$$= 29 \text{ square units.}$$

Therefore, the area of ΔABC is 29 square units.

Question: 17

Show that the poi

Solution:

Given: The points are A(-5, 1), B(5, 5) and C(10, 7).

Note: Three points are collinear if the sum of lengths of any sides is equal to the length of the third side.

$$\begin{aligned} AB &= \sqrt{(5 + 5)^2 + (5 - 1)^2} = \sqrt{100 + 16} \\ &= 2\sqrt{29} \text{ units} \dots\dots(1) \end{aligned}$$

$$\begin{aligned} BC &= \sqrt{(10 - 5)^2 + (7 - 5)^2} = \sqrt{25 + 4} \\ &= \sqrt{29} \text{ units} \dots\dots(2) \end{aligned}$$

$$\begin{aligned} AC &= \sqrt{(10 + 5)^2 + (7 - 1)^2} = \sqrt{225 + 36} \\ &= 3\sqrt{29} \text{ units} \dots\dots(3) \end{aligned}$$

From equations 1, 2 and 3, we have

$$AB + BC = AC$$

Therefore, the three points are collinear.

Question: 18

Find the value of

Solution:

Given: The points are A(-5, 1), B(1, 2) and C(k, 0)

To find: value of k

$$\begin{aligned} AB &= \sqrt{(1 + 5)^2 + (2 - 1)^2} = \sqrt{36 + 1} \\ &= \sqrt{37} \text{ units} \end{aligned}$$

$$BC = \sqrt{(k - 1)^2 + 4}$$

$$AC = \sqrt{(k + 5)^2 + 1}$$

Since the points are collinear, $AB + BC = AC$

$$\Rightarrow \sqrt{37} + \sqrt{(k - 1)^2 + 4} = \sqrt{(k + 5)^2 + 1}$$

Squaring both sides and rearranging,

$$\Rightarrow 37 + (k - 1)^2 + 4 - (k + 5)^2 - 1 = - 2\sqrt{37} \sqrt{(k - 1)^2 + 4}$$

On simplifying,

$$\Rightarrow 40 - 2k + 1 - 10k - 25 = - 2\sqrt{37} \sqrt{(k - 1)^2 + 4}$$

$$\Rightarrow 16 - 12k = - 2\sqrt{37} \sqrt{(k - 1)^2 + 4}$$

$$\Rightarrow 8 - 6k = - \sqrt{37} \sqrt{(k - 1)^2 + 4}$$

Squaring both sides,

$$\Rightarrow 64 - 96k + 36k^2 = 37 \times (k^2 - 2k + 5)$$

$$\Rightarrow 64 - 96k + 36k^2 = 37k^2 - 74k + 185$$

Rearranging,

$$\Rightarrow 37k^2 - 74k + 185 = 36k^2 - 96k + 64$$

$$\Rightarrow k^2 + 22k + 121 = 0$$

$$\Rightarrow (k + 11)^2 = 0$$

$$\Rightarrow k = -11$$

Therefore, the value of k for which the points A, B and C are collinear is -11.

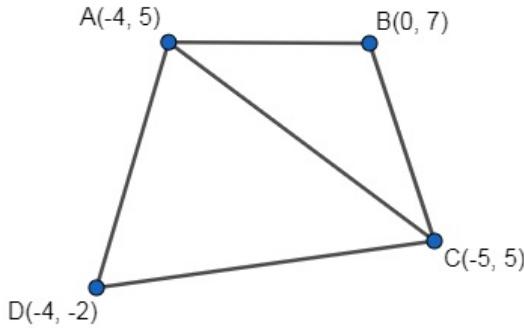

Question: 19

Find the area of

Solution:

Given: The vertices of the quadrilateral are A(-4, 5), B(0, 7), C(5, -5) and D(-4, -2).

Formula: Area of a triangle = $\frac{1}{2} [x_1(y_2 - y_3) + x_2(y_3 - y_1) + x_3(y_1 - y_2)]$

Area of quadrilateral ABCD = Area of Δ ABC + Area of Δ ADC

$$\text{Area of } \Delta \text{ ABC} = \frac{1}{2} [x_1(y_2 - y_3) + x_2(y_3 - y_1) + x_3(y_1 - y_2)]$$

$$= \frac{1}{2} [-4(7 + 5) + 0 + 5(5 - 7)]$$

$$= \frac{1}{2} [-48 - 10]$$

$$= -29$$

Taking modulus (\because area is always positive),

$$\text{Area of } \Delta \text{ ABC} = 29 \text{ sq. units} \dots\dots(1)$$

$$\text{Area of } \Delta \text{ ADC} = \frac{1}{2} [-4(-2 + 5) + -4(-5 - 5) + 5(5 + 2)]$$

$$= \frac{1}{2} [-12 + 40 + 35]$$

$$= 31.5 \text{ sq. units} \dots\dots(2)$$

From 1 and 2,

$$\text{Area of quadrilateral ABCD} = 29 + 31.5$$

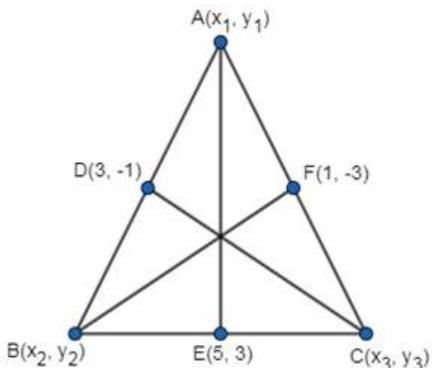

$$= 60.5 \text{ square units.}$$

Therefore, the area of quadrilateral ABCD is 60.5 square units.

Question: 20

Find the area of

Solution:

The figure is as shown above.

$$x_1 + x_2 = 2 \times 3 = 6 \dots\dots(1)$$

$$x_1 + x_3 = 2 \times 1 = 2 \dots\dots(2)$$

$$x_2 + x_3 = 2 \times 5 = 10 \dots\dots(3)$$

Equation 1 - Equation 2 gives us

$$x_2 - x_3 = 4 \dots\dots(4)$$

Equation 3 + Equation 4,

$$2x_2 = 14 \Rightarrow x_2 = 7$$

$$\therefore x_1 = -1 \text{ and } x_3 = 3$$

Similarly,

$$y_1 + y_2 = 2 \times -1 = -2 \dots\dots(5)$$

$$y_1 + y_3 = 2 \times -3 = -6 \dots\dots(6)$$

$$y_2 + y_3 = 2 \times 3 = 6 \dots\dots(7)$$

Equation 5 - Equation 6 gives us

$$y_2 - y_3 = 4 \dots\dots(8)$$

Equation 7 + Equation 8,

$$2y_2 = 10 \Rightarrow y_2 = 5$$

$$\therefore y_1 = -7 \text{ and } y_3 = 1$$

$$\text{Area of } \triangle ABC = \frac{1}{2} [x_1(y_2 - y_3) + x_2(y_3 - y_1) + x_3(y_1 - y_2)]$$

$$= \frac{1}{2} [-1(5 - 1) + 7(1 + 7) + 3(-7 - 5)]$$

$$= \frac{1}{2} [-4 + 56 - 36]$$

$$= 8 \text{ square units}$$

Therefore, the area of $\triangle ABC$ is 8 square units.

Question: 21

Find the coordinates

Solution:

Let $P(x, y)$ be the point that divides the join of $A(-5, 11)$ and $B(4, -7)$ in the ratio $2 : 7$

Formula: If $m_1 : m_2$ is the ratio in which the join of two points is divided by another point (x, y) , then

$$x = \frac{m_1 x_2 + m_2 x_1}{m_1 + m_2}$$

$$y = \frac{m_1 y_2 + m_2 y_1}{m_1 + m_2}$$

Here, $x_1 = -5$, $x_2 = 4$, $y_1 = 11$ and $y_2 = -7$

Substituting,

$$x = \frac{2 \times 4 + 7 \times -5}{2 + 7}$$

$$x = \frac{8 - 35}{9}$$

$$x = \frac{-27}{9}$$

$$\Rightarrow x = -3$$

$$y = \frac{2 \times -7 + 7 \times 11}{2 + 7}$$

$$y = \frac{-14 + 77}{9}$$

$$y = \frac{63}{9}$$

$$\Rightarrow y = 8$$

Therefore, the coordinates of the point which divided the join of A(-5, 11) and B(4, -7) in the ratio 2 : 7 is (-3, 8).

Question: 22

Find the ratio in

Solution:

Let the point which cuts the join of A(4, 5), and B(-10, -2) in the ratio $k : 1$ be P(x, 0)

Formula: If $k : 1$ is the ratio in which the join of two points is divided by another point (x, y), then

$$x = \frac{kx_2 + x_1}{k + 1}$$

$$y = \frac{ky_2 + y_1}{k + 1}$$

Taking for the y co-ordinate,

$$0 = \frac{k \times -2 + 5}{k + 1}$$

$$\Rightarrow 2k = 5$$

$$\Rightarrow k = \frac{5}{2}$$

$$\text{Therefore, } x = \frac{\frac{5}{2} \times -10 + 4}{\frac{5}{2} + 1}$$

$$x = \frac{-50 + 8}{5 + 2}$$

$$x = \frac{-42}{7}$$

$$x = -6$$

Therefore, the ratio in which x-axis cuts the join of the points A(4, 5) and B(-10, -2) is 5 : 2 and the point of intersection is (-6, 0).

Question: 23

In what ratio is

Solution:

Let the point which cuts the join of A(-4, 2) and B(8, 3) in the ratio k : 1 be P(0, y)

Formula: If k : 1 is the ratio in which the join of two points are divided by another point (x, y), then

$$x = \frac{kx_2 + x_1}{k + 1}$$

$$y = \frac{ky_2 + y_1}{k + 1}$$

Taking for the x co-ordinate,

$$0 = \frac{k \times 8 + (-4)}{k + 1}$$

$$\Rightarrow 8k = 4$$

$$\Rightarrow k = \frac{1}{2}$$

$$\text{Therefore, } y = \frac{\frac{1}{2} \times 3 + 2}{\frac{1}{2} + 1}$$

$$y = \frac{3 + 4}{1 + 2}$$

$$y = \frac{7}{3}$$

Therefore, the ratio in which the line segment joining the points A(-4, 2) and B(8, 3) divided by the y-axis is 1 : 2 and the point of intersection is $(0, \frac{7}{3})$

Exercise : 20B

Question: 1

Find the slope of

Solution:

We know that the slope of a given line is given by

Slope = $\tan \theta$ Where θ = angle of inclination

(i) Given that $\theta = 30^\circ$

$$\text{Slope} = \tan(30^\circ) = \frac{1}{\sqrt{3}}$$

(ii) Given that $\theta = 120^\circ$

$$\text{Slope} = \tan(120^\circ) = \tan(90^\circ + 30^\circ) = -\cot(30^\circ) = -\sqrt{3}$$

(iii) Given that $\theta = 135^\circ$

$$\text{Slope} = \tan(135^\circ) = \tan(90^\circ + 45^\circ) = -\cot(45^\circ) = -1$$

(iv) Given that $\theta = 90^\circ$

Slope = $\tan(90^\circ) = \infty$

Question: 2

Find the inclination

Solution:

We know that the slope of a given line is given by

Slope = $\tan \theta$ Where θ = angle of inclination

$$(i) \tan \theta = \sqrt{3} \Rightarrow \theta = \tan^{-1}(\sqrt{3}) \Rightarrow \theta = 60^\circ$$

$$(ii) \tan \theta = \frac{1}{\sqrt{3}} \Rightarrow \theta = \tan^{-1}\left(\frac{1}{\sqrt{3}}\right) \Rightarrow \theta = 30^\circ$$

$$(iii) \tan \theta = 1 \Rightarrow \theta = \tan^{-1}(1) \Rightarrow \theta = 45^\circ$$

$$(iv) \tan \theta = -1 \Rightarrow \theta = \tan^{-1}(-1) \Rightarrow \theta = -45^\circ = 315^\circ$$

$$(v) \tan \theta = -\sqrt{3} \Rightarrow \theta = \tan^{-1}(-\sqrt{3}) \Rightarrow \theta = -60^\circ = 300^\circ$$

Question: 3

Find the slope of

Solution:

If a line passing through (x_1, y_1) & (x_2, y_2) then slope of the line is given by $\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1}\right)$

(i) Given points are $(0, 0)$ and $(4, -2)$

$$\text{slope} = \left(\frac{-2 - 0}{4 - 0}\right) = \frac{-1}{2}$$

(ii) Given points are $(0, -3)$ and $(2, 1)$

$$\text{slope} = \left(\frac{1 - (-3)}{2 - 0}\right) = 2$$

(iii) Given points are $(2, 5)$ and $(-4, -4)$

$$\text{slope} = \left(\frac{-4 - 5}{-4 - 2}\right) = \frac{3}{2} = 1.5$$

(iv) Given points are $(-2, 3)$ and $(4, -6)$

$$\text{slope} = \left(\frac{-6 - 3}{4 + 2}\right) = \frac{-3}{2} = -1.5$$

Question: 4

If the slope of t

Solution:

If a line passing through (x_1, y_1) & (x_2, y_2) then slope of the line is given by $\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1}\right)$.

Given points are A($x, 2$) and B($6, -8$), and the slope is

$$\frac{-5}{4}$$

$$\Rightarrow \left(\frac{-8 - 2}{6 - x}\right) = \frac{-5}{4} \Rightarrow \left(\frac{-10}{6 - x}\right) = \frac{-5}{4} \Rightarrow -40 = -30 + 5x \Rightarrow 5x = -10 \Rightarrow x = -2$$

Question: 5

Show that the line

Solution:

We know that for two lines to be parallel, their slope must be the same.

Given points are A(5,6),B(2,3) and C(9,-2),D(6,-5)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\Rightarrow \left(\frac{3 - 6}{2 - 5} \right) = \left(\frac{-5 + 2}{6 - 9} \right) \Rightarrow \left(\frac{-3}{-3} \right) = \left(\frac{-3}{-3} \right) \Rightarrow 1 = 1$$

Hence proved.

Question: 6

Find the value of

Solution:

We know that for two lines to be parallel, their slope must be the same. The given points are A(3,x),B(2,7) and C(-1,4),D(0,6)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\Rightarrow \left(\frac{6 - 4}{0 + 1} \right) = \left(\frac{7 - x}{2 - 3} \right) \Rightarrow \left(\frac{2}{1} \right) = \left(\frac{7 - x}{-1} \right) \Rightarrow -2 = 7 - x \Rightarrow x = 9$$

Question: 7

Show that the lin

Solution:

For two lines to be perpendicular, their product of slope must be equal to -1.

Given points are A(-2,6),B(4,8) and C(3,-3),D(5,-9)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

Slope of line AB \times slope of line CD = -1

$$\Rightarrow \left(\frac{8 - 6}{4 + 2} \right) \times \left(\frac{-9 + 3}{5 - 3} \right) = -1 \Rightarrow \left(\frac{2}{6} \right) \times \left(\frac{-6}{2} \right) = -1 \Rightarrow -1 = -1 \Rightarrow \text{LHS} = \text{RHS}$$

Question: 8

If A(2, -5), B(-2

Solution:

For two lines to be perpendicular, their product of slope must be equal to -1.

Given points are A(2, -5),B(-2, 5) and C(x, 3),D(1, 1)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

\Rightarrow Slope of line AB is equal to

$$\left(\frac{5 + 5}{-2 - 2} \right) = \left(\frac{10}{-4} \right) = \left(\frac{-5}{2} \right) = -2.5$$

And the slope of line CD is equal to

$$\left(\frac{1 - 3}{1 - x} \right) = \left(\frac{-2}{1 - x} \right)$$

Their product must be equal to -1

the slope of line AB \times Slope of line CD = -1

$$\Rightarrow -2.5 \times \left(\frac{-2}{1-x} \right) = -1 \Rightarrow 5 = x-1 \Rightarrow x = 6$$

Question: 9

Without using Pyt

Solution:

The ΔABC is made up of three lines, AB, BC and CA

For a right angle triangle, two lines must be at 90° so they are perpendicular to each other.

Checking for lines AB and BC

For two lines to be perpendicular, their product of slope must be equal to -1.

Given points A(1, 2), B(4, 5) and C(6, 3)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\text{Slope of AB} = \left(\frac{5-2}{4-1} \right) = \frac{3}{3} = 1$$

$$\text{Slope of BC} = \left(\frac{3-5}{6-4} \right) = \frac{-2}{2} = -1$$

$$\text{Slope of CA} = \left(\frac{3-2}{6-1} \right) = \frac{1}{5} = 0.2$$

Checking slopes of line AB and BC

$$1 \times -1 = -1$$

So AB is Perpendicular to BC .

So it is a right angle triangle.

Question: 10

Using slopes show

Solution:

For three points to be collinear, the slope of all pairs must be equal, that is the slope of AB = slope of BC = slope of CA

Given points are A(6, -1), B(5, 0) and C(2, 3)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\text{Slope of AB} = \left(\frac{0+1}{5-6} \right) = \frac{1}{-1} = -1$$

$$\text{Slope of BC} = \left(\frac{3-0}{2-5} \right) = \frac{3}{-3} = -1$$

$$\text{Slope of CA} = \left(\frac{3+1}{2-6} \right) = \frac{4}{-4} = -1$$

Therefore slopes of AB, BC and CA are equal, so Points A,B,C are collinear.

Question: 11

Using slopes, fin

Solution:

For three points to be collinear, the slope of all pairs must be equal, that is the slope of AB = slope of BC = slope of CA

Given points are A(5, 1), B(1, -1) and C(x, 4)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\text{Slope of AB} = \left(\frac{-1-1}{1-5} \right) = \frac{-2}{-4} = \frac{1}{2} = 0.5$$

$$\text{The slope of BC} = \left(\frac{4+1}{x-1} \right) = \left(\frac{5}{x-1} \right)$$

$$\text{Slope of CA} = \left(\frac{4-1}{x-5} \right) = \left(\frac{3}{x-5} \right)$$

The slope of all lines must be the same

$$\Rightarrow 0.5 = \left(\frac{5}{x-1} \right) \Rightarrow 0.5x - 0.5 = 5 \Rightarrow 0.5x = 5.5 \Rightarrow x = 11$$

Note:- We can use any two points to get the value of "x".

Question: 12

Using slopes show

Solution:

A rectangle has all sides perpendicular to each other, so the product of slope of every adjacent line is equal to -1.

Given point in order are A(-4, -1), B(-2, -4), C(4, 0) and D(2, 3)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\text{Slope of AB} = \left(\frac{-4+1}{-2+4} \right) = \frac{-3}{2}$$

$$\text{Slope of BC} = \left(\frac{0+4}{4+2} \right) = \frac{4}{6} = \frac{2}{3}$$

$$\text{The slope of CD} = \left(\frac{3-0}{2-4} \right) = \frac{3}{-2}$$

$$\text{Slope of DA} = \left(\frac{3+1}{2+4} \right) = \frac{4}{6} = \frac{2}{3}$$

\Rightarrow slope of AB \times slope of BC

$$\Rightarrow \frac{-3}{2} \times \frac{2}{3} = -1$$

Hence AB is perpendicular to BC

Slope of BC \times slope of CD

$$\frac{2}{3} \times \frac{3}{-2} = -1$$

Hence BC is perpendicular to CD

Slope of CD \times slope of DA

$$\Rightarrow \frac{3}{-2} \times \frac{2}{3} = -1$$

Hence CD is perpendicular to DA

Slope of DA \times slope of AB

$$\Rightarrow \frac{2}{3} \times \frac{-3}{2} = -1$$

Hence DA is perpendicular to AB.

All angles are 90° .

So this is a rectangle ABCD.

Question: 13

Using slopes. Pro

Solution:

The property of parallelogram states that opposite sides are equal.

We have 4 sides as AB, BC, CD, DA

Given points are A(-2, -1), B(1, 0), C(4, 3) and D(1, 2)

AB and CD are opposite sides, and BC and DA are the other two opposite sides.

So slopes of AB = CD and slopes BC = DA

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\text{Slope of AB} = \left(\frac{0+1}{1+2} \right) = \frac{1}{3}$$

$$\text{The slope of BC} = \left(\frac{3-0}{4-1} \right) = \frac{3}{3} = 1$$

$$\text{The slope of CD} = \left(\frac{2-3}{1-4} \right) = \frac{-1}{-3} = \frac{1}{3}$$

$$\text{Slope of DA} = \left(\frac{2+1}{1+2} \right) = \frac{3}{3} = 1$$

Therefore the Slope of AB = Slope of CD and

The slope of BC = Slope of DA

Also, the product of slope of two adjacent sides is not equal to -1, therefore it is not a rectangle.

Hence ABCD is a parallelogram.

Question: 14

If the three point

Solution:

For the lines to be in a line, the slope of the adjacent lines should be the same.

Given points are A(h, k), B(x₁, y₁) and C(x₂, y₂)

So slope of AB = BC = CA

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\text{Slope of AB} = \left(\frac{y_1 - k}{x_1 - h} \right)$$

$$\text{Slope of BC} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\text{Slope of CA} = \left(\frac{y_2 - k}{x_2 - h} \right)$$

$$\Rightarrow \left(\frac{y_1 - k}{x_1 - h} \right) = \left(\frac{y_2 - y_1}{x_2 - x_1} \right) = \left(\frac{y_2 - k}{x_2 - h} \right)$$

Now Cross multiplying the first two equality,

$$(y_1 - k)(x_2 - x_1) = (x_1 - h)(y_2 - y_1)$$

$$\Rightarrow (h - x_1)(y_2 - y_1) = (k - y_1)(x_2 - x_1)$$

Hence proved.

Question: 15

If the points A(a

Solution:

Given points are A(a,0),B(0,b) and P(x,y)

For three points to be collinear, the slope of all pairs must be equal, that is the slope of AB = slope of BP = slope of PA.

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\text{Slope of AB} = \left(\frac{b-0}{0-a} \right) = \frac{b}{-a}$$

$$\text{Slope of BP} = \left(\frac{y-b}{x-0} \right) = \frac{y-b}{x}$$

$$\text{Slope of PA} = \left(\frac{y-0}{x-a} \right) = \frac{y}{x-a}$$

Now Slope of AB = BP = PA

$$\frac{b}{-a} = \frac{y-b}{x} = \frac{y}{x-a}$$

Using the first two equality

$$\Rightarrow \frac{b}{-a} = \frac{y-b}{x} \Rightarrow bx = -a(y-b) \Rightarrow bx = -ay + ab$$

Dividing the equation by "ab", We get

$$\frac{x}{a} = -\frac{y}{b} + 1 \Rightarrow \frac{x}{a} + \frac{y}{b} = 1$$

Hence proved.

Question: 16

A line passes thr

Solution:

For the line to make an obtuse angle with X-axis, the angle of the line should be greater than 90°

For the angle to be greater than 90°, $\tan\theta$ must be negative

Where $\tan\theta$ is the slope of the line.

Given points are A(4, -6) and B(-2, -5)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\text{The slope of line AB is } \left(\frac{-5+6}{-2-4} \right) = \frac{1}{-6} = \frac{-1}{6}$$

Which is less than 0, hence negative.

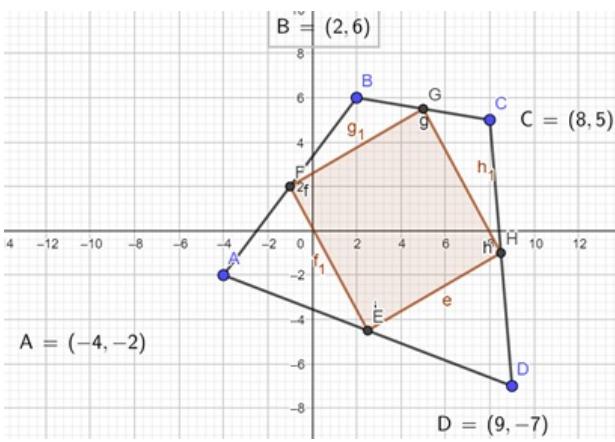

$$\Rightarrow \tan\theta = \frac{-1}{6} \quad (0, \tan\theta \text{ is negative in 2nd quadrant whose angle is } >90^\circ)$$

So line AB makes obtuse angle(>90°) with the X-axis.

Question: 17

The vertices of a

Solution:

The vertices of the given quadrilateral are A(-4, -2) B(2, 6), C(8, 5) and D(9, -7)

The mid point of a line A(x₁,y₁) and B(x₂,y₂) is found out by $\left(\frac{x_1+x_2}{2}, \frac{y_1+y_2}{2}\right)$

$$\text{Now midpoint of AB} = \left(\frac{-4+2}{2}, \frac{-2+6}{2}\right) = (-1, 2)$$

$$\text{The midpoint of BC} = \left(\frac{2+8}{2}, \frac{6+5}{2}\right) = (5, 5.5)$$

$$\text{The midpoint of CD} = \left(\frac{8+9}{2}, \frac{5-7}{2}\right) = (8.5, -1)$$

$$\text{Midpoint of DA} = \left(\frac{-4+9}{2}, \frac{-2-7}{2}\right) = (2.5, -4.5)$$

So now we have four points

P(-1, 2), Q(5, 5.5), R(8.5, -1), S(2.5, -4.5)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1}\right)$$

$$\text{Slope of PQ} = \left(\frac{5.5-2}{5+1}\right) = \frac{3.5}{6} = \frac{7}{12}$$

$$\text{Slope of QR} = \left(\frac{-1-5.5}{8.5-5}\right) = \frac{-6.5}{3.5} = \frac{-1.3}{0.7} = \frac{-13}{7}$$

$$\text{Slope of RS} = \left(\frac{-4.5+1}{2.5-8.5}\right) = \frac{-3.5}{-6} = \frac{7}{12}$$

$$\text{Slope of SP} = \left(\frac{-4.5-2}{2.5+1}\right) = \frac{-6.5}{3.5} = \frac{-13}{7}$$

Now we can observe that slope of PQ = RS and slope of QR = SP

Which shows that line PQ is parallel to RS and line QR is parallel to SP

Also, the product of two adjacent lines is not equal to -1

Therefore PQRS is a parallelogram.

Question: 18

Find the slope of

Solution:

According to the given figure, the angle made by the line from X-axis is $90 + 30 = 120^\circ$

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1}\right)$$

We also know that slope of a line is equal to $\tan\theta$, Where

$$\theta = 120^\circ$$

$$\tan(120^\circ) = \tan(90^\circ + 30^\circ) = -\cot(30^\circ) = -\sqrt{3}$$

Therefor the slope of the given line is $-\sqrt{3}$.

Question: 19

Find the angle be

Solution:

To find out the angle between two lines, the angle is equal to the difference in θ .

$$\text{The slope of a line} = \tan\theta = \left(\frac{y_2-y_1}{x_2-x_1}\right)$$

So slope of the first line $= \sqrt{3} = \tan\theta_1 \Rightarrow \tan\theta_1 = \sqrt{3} \Rightarrow \theta_1 = \tan^{-1}(\sqrt{3}) \Rightarrow \theta_1 = 60^\circ$

$$\text{The slope of the second line} = \frac{1}{\sqrt{3}} = \tan\theta_2 \Rightarrow \theta_2 = \tan^{-1}\left(\frac{1}{\sqrt{3}}\right) \Rightarrow \theta_2 = 30^\circ$$

Now the difference between the two lines is $\theta_1 - \theta_2$

$$= 60^\circ - 30^\circ$$

$$= 30^\circ$$

Question: 20

Find the angle be

Solution:

We know that if slope of two lines are m_1 and m_2 respectively, then the angle between them is given by

$$\tan\theta = \frac{m_2 - m_1}{1 + m_1 m_2}$$

Here $m_2 = 2 + \sqrt{3}$ and $m_1 = 2 - \sqrt{3}$

$$\tan\theta = \frac{(2 + \sqrt{3}) - (2 - \sqrt{3})}{1 + (2 + \sqrt{3})(2 - \sqrt{3})} = \frac{2\sqrt{3}}{1 + (2^2 - (\sqrt{3})^2)} = \frac{2\sqrt{3}}{1 + 1} = \sqrt{3}$$

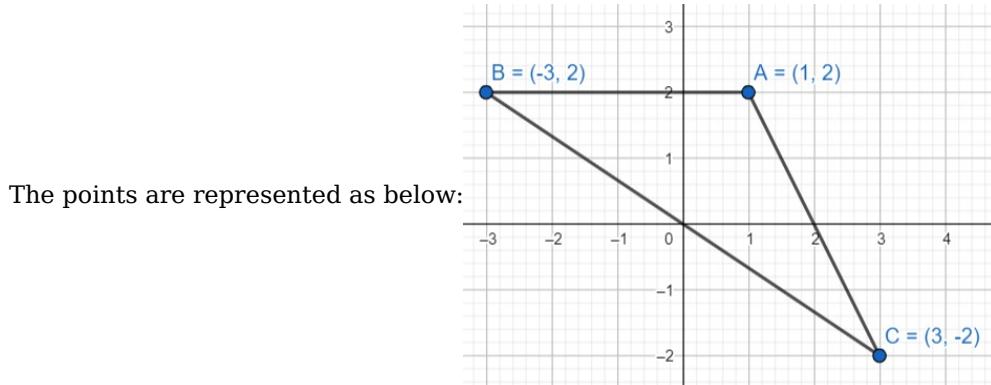

$$\tan\theta = \sqrt{3} \Rightarrow \theta = \tan^{-1}(\sqrt{3}) \Rightarrow \theta = 60^\circ$$

Where θ is the angle between two lines.

Question: 21

If A(1, 2), B(-3,

Solution:

The points are represented as below:

Now let us find

the slope of line AC, $\text{Slope}_{AC} = \frac{-2-2}{3-1} = \frac{-4}{2} = -2$ The line AB is parallel to x-axis. We can see that, slope of AC = $-\tan(A)-2 = -\tan A$ Now, finding the slope of BC,
 $\text{Slope}_{BC} = \frac{-2-2}{3-(-3)} = \frac{-4}{6} = \frac{-2}{3}$ The line AB is parallel to x-axis. Therefore, slope of AB = $-\tan(B)-2/3 = -\tan B$ Now, $\tan C = -\frac{\tan A + \tan B}{1 - \tan A \cdot \tan B}$ Putting the values, we will

get, $\tan C = 8$.

Question: 22

If θ is the angle

Solution:

The given points are A(0,0), B(2,3) and C(2,-2), D(3,5).

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

The slope of line AB is $\left(\frac{3-0}{2-0} \right) = \frac{3}{2} = m_1$

And the slope of line CD is $\left(\frac{5+2}{3-2} \right) = 7 = m_2$

We know that angle between two lines with their slopes as m_1 and m_2 is given by

$$\begin{aligned}\tan \theta &= \frac{m_2 - m_1}{1 + m_1 m_2} \\ &= \frac{7 - \frac{3}{2}}{1 + 7 \times \frac{3}{2}} = \frac{\frac{14-3}{2}}{\frac{2+21}{2}} = \frac{11}{23} \Rightarrow \tan \theta = \frac{11}{23}\end{aligned}$$

Hence proved.

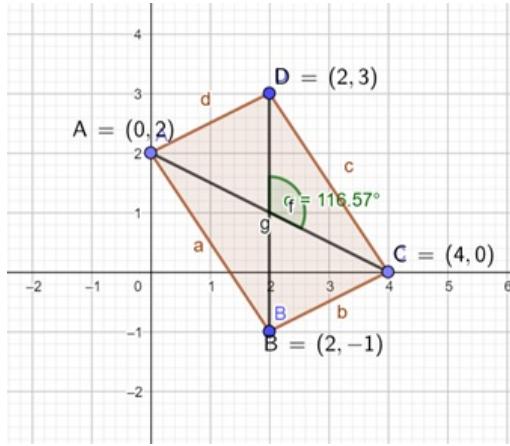

Question: 23

If θ is the angle

Solution:

Given points of the parallelogram are A(0, 2), B(2,-1), C(4, 0) and D(2, 3)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

The slope of diagonal AC = $\left(\frac{0-2}{4-0} \right) = \frac{-2}{4} = \frac{-1}{2} = m_1$

The slope of diagonal BD = $\left(\frac{3+1}{2-2} \right) = \frac{4}{0} = \infty = m_2$

So diagonal BD is perpendicular to X-axis. Hence it is parallel to Y-axis.

Product of slope of two diagonals is equal to -1.

$$m_1 \times m_2 = -1 \Rightarrow \left(\frac{-1}{2} \right) \times \tan \theta = -1 \Rightarrow \tan \theta = 2$$

Hence proved.

Question: 24

Show that the poi

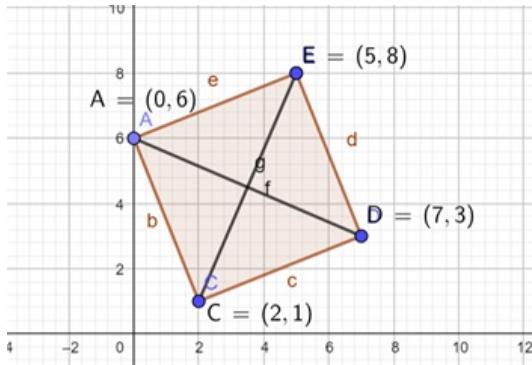

Solution:

In a square, all sides are perpendicular to the adjacent side, so the product of slope of two adjacent sides is -1.

Let the position of point D(a,b).

Given points of the square are A(0, 6), B(2, 1), C(7, 3) and D(a,b).

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\text{The slope of line } AB = \left(\frac{1-6}{2-0} \right) = \frac{-5}{2} = m_1$$

$$\text{The slope of line } BC = \left(\frac{3-1}{7-2} \right) = \frac{2}{5} = m_2$$

$$\text{The slope of line } CD = \left(\frac{b-3}{a-7} \right) = m_3$$

$$\text{The slope of line } DA = \left(\frac{b-6}{a-0} \right) = \frac{b-6}{a} = m_4$$

$$\text{The slope of diagonal } AC = \left(\frac{3-6}{7-0} \right) = \frac{-3}{7}$$

$$\text{The slope of diagonal } BD = m_5$$

(i) We know that in a square, two diagonals are perpendicular to each other, therefore

$$\text{The slope of diagonal } AC \times \text{slope of diagonal } BD = -1$$

$$m_5 \times \frac{-3}{7} = -1 \Rightarrow m_5 = \frac{7}{3}$$

So the slope of diagonal BD is 7/3.

(ii) We know that midpoint of diagonal AC = midpoint of diagonal BD

$$0\left(\frac{x_1+x_2}{2}, \frac{y_1+y_2}{2}\right) \text{ and comparing x and y coordinates respectively.}$$

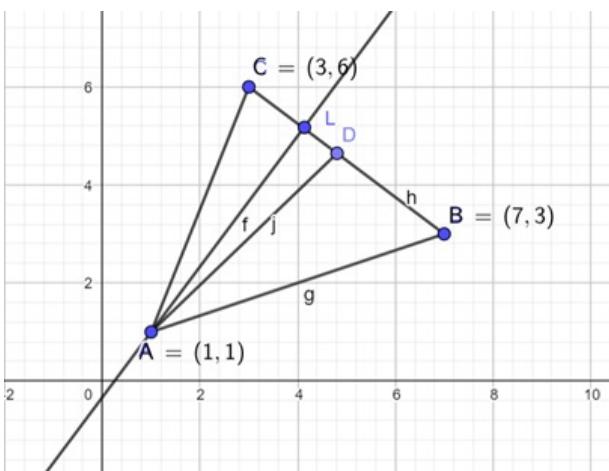

$$\left(\frac{7+0}{2}, \frac{3+6}{2}\right) = \left(\frac{a+2}{2}, \frac{b+1}{2}\right) \Rightarrow \left(\frac{7}{2}, \frac{9}{2}\right) = \left(\frac{a+2}{2}, \frac{b+1}{2}\right) \Rightarrow \frac{7}{2} = \frac{a+2}{2} \& \frac{9}{2} = \frac{b+1}{2} \Rightarrow a = 5 \& b = 8$$

So coordinate of the point D(5,8).

Question: 25

A(1, 1), B(7, 3)

Solution:

Given points are

A(1, 1), B(7, 3) and C(3, 6)

$$\text{slope} = \left(\frac{y_2 - y_1}{x_2 - x_1} \right)$$

$$\text{Slope of line BC} = \left(\frac{3-6}{7-3} \right) = \frac{-3}{4}$$

$$(i) \text{ As D is the midpoint of BC, coordinate of D are } D \left(\frac{x_1+x_2}{2}, \frac{y_1+y_2}{2} \right)$$

$$= \left(\frac{7+3}{2}, \frac{3+6}{2} \right) = \left(5, \frac{9}{2} \right)$$

$$\text{Now the slope of AD} = \left(\frac{\frac{9}{2}-1}{5-1} \right) = \left(\frac{\frac{7}{2}}{4} \right) = \frac{3.5}{4}$$

(ii) As AL is perpendicular to BC

The slope of AL \times slope of BC = -1

Let slope of AL be m_1

$$\frac{-3}{4} \times m_1 = -1 \Rightarrow m_1 = \frac{4}{3}$$

So Slope of line AL is $\frac{4}{3}$.

Exercise : 20C

Question: 1

Find the equation

Solution:

(i) Equation of line parallel to x - axis is given by $y = \text{constant}$, as the y - coordinate of every point on the line parallel to x - axis is 4,i.e. constant. Now the point lies above x - axis means in positive direction of y - axis,

So, the equation of line is given as $y = 4$.

(ii) Equation of line parallel to x - axis is given by $y = \text{constant}$, as the y - coordinate of every point on the line parallel to x - axis is - 5 i.e. constant. Now the point lies below x - axis means in negative direction of y - axis,

So, the equation of line is given as $y = - 5$.

Question: 2

Find the equation

Solution:

(i) Equation of line parallel to y - axis is given by $x = \text{constant}$, as the x - coordinate of every point on the line parallel to y - axis is 6 i.e. constant. Now the point lies to the right of y - axis means in the positive direction of x - axis,

So, required equation of line is $x = 6$.

(ii) Equation of line parallel to y - axis is given by $x = \text{constant}$, as the x - coordinate of every point on the line parallel to y - axis is - 3. Now point lies to the left of y - axis means in the negative direction of x - axis,

So, required equation of line is given as $x = - 3$.

Question: 3

Find the equation

Solution:

Equation of line parallel to x - axis is given by $y = \text{constant}$, as x - coordinate of every point on the line parallel to y - axis is - 3 i.e. constant.

So, the required equation of line is $y = - 3$.

Question: 4

Find the equation

Solution:

Equation of line parallel to x - axis (horizontal) is $y = \text{constant}$, as y - coordinate of every point on the line parallel to x - axis is - 2 i.e. constant. Therefore equation of the line parallel to x - axis and passing through (4, - 2) is $y = - 2$.

Question: 5

Find the equation

Solution:

Equation of line parallel to y - axis (vertical) is given by $x = \text{constant}$, as x - coordinate is constant for every point lying on line i.e. 6.

So, the required equation of line is given as $x = 6$.

Question: 6

Find the equation

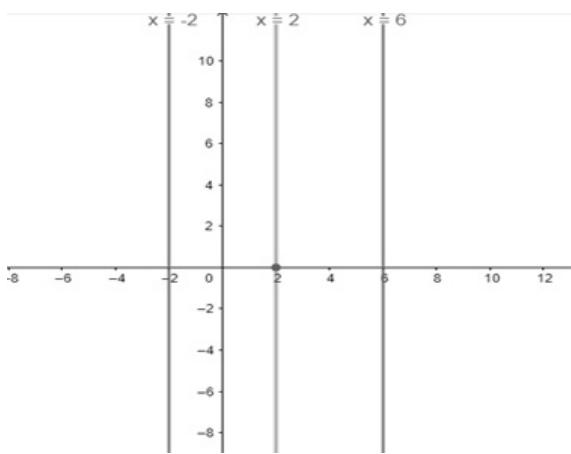

Solution:

For the equation of line equidistant from both lines, we will find point through which line passes and is equidistant from both line.

As any point lying on $x = - 2$ line is (- 2, 0) and on $x = 6$ is (6, 0), so mid - point is

$$(x, y) = \left(\frac{-2 + 6}{2}, \frac{0 + 0}{2} \right)$$

$$(x, y) = (2, 0)$$

So, equation of line is $x = 2$.

Question: 7

Find the equation

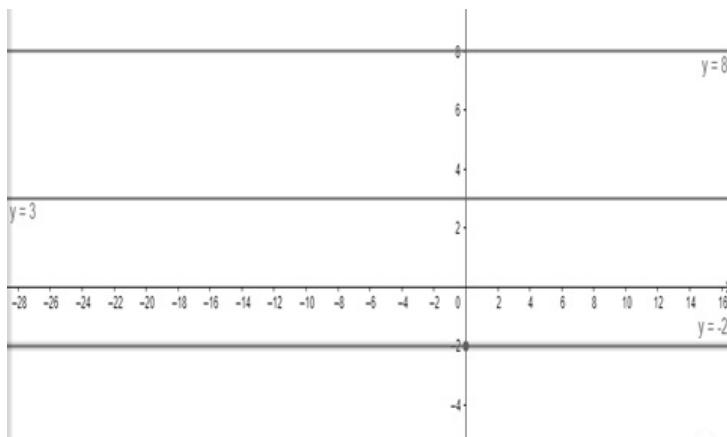

Solution:

For the equation of line equidistant from both lines, we will find point through which line passes and is equidistant from both line.

As any point lying on $y = 8$ line is $(0, 8)$ and on $y = -2$ is $(0, -2)$, so mid-point is

$$(x, y) = \left(\frac{0+0}{2}, \frac{8-2}{2} \right)$$

$$(x, y) = (0, 3)$$

So, equation of line is $y = 3$.

Question: 8 A

Find the equation

Solution:

As slope is given $m = 4$ and passing through $(5, -7)$. using slope - intercept form of equation of line, we will find value of intercept first

$$y = mx + c \dots\dots\dots(1)$$

$$-7 = 4(5) + c$$

$$-7 = 20 + c$$

$$c = -7 - 20$$

$$c = -27$$

Putting the value of c in equation (1), we have

$$y = 4x + (-27)$$

$$y = 4x - 27$$

$$4x - y - 27 = 0$$

So, the required equation of line is $4x - y - 27 = 0$.

Question: 8 B

Find the equation

Solution:

As slope is given $m = -3$ and line is passing through point $(-2, 3)$. Using slope - intercept form of equation of line, we will find intercept first

$$y = mx + c \dots\dots\dots\dots\dots(1)$$

$$3 = -3(-2) + c$$

$$3 = 6 + c$$

$$c = 3 - 6$$

$$c = -3$$

Putting the value of c in equation (1), we have

$$y = -3x + (-3)$$

$$y = -3x - 3$$

$$3x + y + 3 = 0$$

So, the required equation of line is $3x + y + 3 = 0$.

Question: 8 C

Find the equation

Solution:

We have given angle so we have to find slope first given by $m = \tan\theta$.

$$m = \tan\theta \Rightarrow \tan\left(\frac{2\pi}{3}\right) = \tan\left(\pi - \frac{\pi}{3}\right)$$

$$m \Rightarrow -\tan\left(\frac{\pi}{3}\right) = -(\sqrt{3}) \quad (\text{tan } x \text{ is negative in II quadrant})$$

$$m = -\sqrt{3}$$

Now the line is passing through the point $(0, 2)$. Using the slope - intercept form of the equation of the line, we will find intercept

$$y = mx + c \dots\dots\dots\dots\dots(1)$$

$$2 = -(\sqrt{3})(0) + c \Rightarrow c = 2$$

Putting the value of c in equation (1), we have

$$y = -(\sqrt{3})x + 2$$

$$-(\sqrt{3})x - y + 2 = 0$$

So, required equation of line is $-(\sqrt{3})x - y + 2 = 0$.

Question: 9

$$m = \tan 30^\circ$$

$$m = \frac{1}{\sqrt{3}}$$

Now the line is passing through the point (0, 5). Using slope - intercept form of the equation of the line, we will find the intercept

$$y = mx + c \dots\dots\dots\dots\dots(1)$$

$$5 = \frac{1}{\sqrt{3}}(0) + c \Rightarrow c = 5$$

Putting the value of c in equation (1), we have

$$y = \frac{1}{\sqrt{3}}x + 5$$

$$x - (\sqrt{3})y + 5\sqrt{3} = 0$$

$$\text{So, required equation of line is } x - (\sqrt{3})y + 5\sqrt{3} = 0.$$

Question: 10

$$m = \tan 150^\circ$$

$$m = \tan(180^\circ - 30^\circ) \Rightarrow -\tan 30^\circ = -\frac{1}{\sqrt{3}} \quad (\tan(180^\circ - \theta) \text{ is in II quadrant, tanx is negative})$$

Now the line is passing through the point (3, -5). Using the slope - intercept form of the equation of the line, we will find the intercept

$$y = mx + c \dots\dots\dots\dots\dots(1)$$

$$-5 = -\frac{1}{\sqrt{3}}(3) + c \Rightarrow c = -5 + \sqrt{3}$$

Putting the value of c in equation (1), we have

$$y = -\frac{1}{\sqrt{3}}x + (-5 + \sqrt{3})$$

$$x + (\sqrt{3})y + 5\sqrt{3} - 3 = 0$$

$$\text{So, required equation of line is } x + (\sqrt{3})y + 5\sqrt{3} - 3 = 0.$$

Question: 11

$$m = \tan 120^\circ$$

$$m = \tan(180^\circ - 60^\circ) \Rightarrow -\tan 60^\circ = -(\sqrt{3})$$

($\tan(180^\circ - \theta)$ is in II quadrant, tanx is negative)

Now equation of line passing through origin is given as $y = mx$

$$y = -(\sqrt{3})x$$

$$(\sqrt{3})x + y = 0$$

$$\text{So, required equation of line is } (\sqrt{3})x + y = 0$$

Question: 12

$$m = \tan\theta$$

$$m = \tan 60^\circ \Rightarrow \sqrt{3}$$

Now using slope intercept form of the equation of a line

$$y = mx + c$$

$$y = (\sqrt{3})x + 5$$

$$(\sqrt{3})x - y + 5 = 0$$

So, the required equation of line is $(\sqrt{3})x - y + 5 = 0$.

Question: 13

$$m = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{4 - 7}{-2 - 3} = \frac{-3}{-5}$$

$$m = \frac{3}{5}$$

Now using the slope - intercept form, we will find intercept for a line passing through (4, - 5)

$$y = mx + c \dots\dots\dots\dots\dots(1)$$

$$-5 = \frac{3}{5}(4) + c \Rightarrow -5 - \frac{12}{5} = c$$

$$c = \frac{-25 - 12}{5} \Rightarrow c = -\frac{37}{5}$$

Putting value in equation (1)

$$y = \frac{3}{5}(x) + \left(-\frac{37}{5}\right) \Rightarrow 3x - 5y - 37 = 0$$

So, the required equation of line is $3x - 5y - 37 = 0$.

Question: 14

As two points passing through line perpendicular to the line are given, we will calculate slope using two points. Let slopes of the two lines be m_1 and m_2 .

$$m_1 = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{6 - 5}{-3 - 2} = -\frac{1}{5}$$

$$m_1 = -\frac{1}{5}$$

Now the slope of the equation can be found using

$m_1 m_2 = -1$ where m_1, m_2 are slopes of two perpendicular lines

$$\frac{-1}{5} \cdot m_2 = -1 \Rightarrow m_2 = 5$$

Using slope - intercept form we will find intercept for line passing through (- 3, 5)

$$y = mx + c \dots\dots\dots\dots\dots(1)$$

$$5 = 5(-3) + c$$

$$c = 5 + 15$$

$$c = 20$$

Putting value in equation (1)

$$y = 5x + 20$$

$$5x - y + 20 = 0$$

So, the required equation of line $5x - y + 20 = 0$.

Question: 15 A

Slope of equation can be calculated using

$$m = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{-7 - (-2)}{-5 - 3} = \frac{-5}{-8}$$

$$m = \frac{5}{8}$$

Now using two point form of the equation of a line

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1}(x - x_1) \text{ where } \frac{y_2 - y_1}{x_2 - x_1} = \text{slope of line}$$

$$y - (-2) = \frac{5}{8}(x - 3) \Rightarrow 8(y + 2) = 5(x - 3)$$

$$8y + 16 = 5x - 15$$

$$5x - 8y - 16 - 15 = 0$$

$$5x - 8y - 31 = 0$$

So, required equation of line is $5x - 8y - 31 = 0$.

Question: 15 B

The slope of the equation can be calculated using

$$m = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{-4 - 1}{2 - (-1)} = \frac{-5}{3}$$

$$m = -\frac{5}{3}$$

Now using two point form of the equation of a line

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1}(x - x_1) \text{ where } \frac{y_2 - y_1}{x_2 - x_1} = \text{slope of line}$$

$$y - 1 = \frac{-5}{3}(x - (-1)) \Rightarrow 3(y - 1) = -5(x + 1)$$

$$3y - 3 + 5x + 5 = 0$$

$$5x + 3y + 2 = 0$$

So, required equation of line is $5x + 3y + 2 = 0$.

Question: 15 C

The slope of the equation can be calculated using

$$m = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{-3 - 3}{-5 - 5} = \frac{-6}{-10}$$

$$m = \frac{3}{5}$$

Now using two point form of the equation of a line

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1}(x - x_1) \text{ where } \frac{y_2 - y_1}{x_2 - x_1} = \text{slope of line}$$

$$y - 3 = \frac{3}{5}(x - 5) \Rightarrow 5(y - 3) = 3(x - 5)$$

$$3x - 15 - 5y + 15 = 0$$

$$3x - 5y = 0$$

So, required equation of line is $3x - 5y = 0$.

Question: 15 D

The slope of the equation can be calculated using

$$m = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{b - b}{-a - a} = 0$$

$m = 0$ (Horizontal line)

Now using two point form of the equation of a line

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1}(x - x_1)$$

$$y - b = 0(x - a)$$

$$y = b$$

So, required equation of line is $y = b$.

Question: 16

$$m = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{(\sqrt{6}) - (\sqrt{3})}{(\sqrt{2}) - 1} = \frac{(\sqrt{3})(\sqrt{2} - 1)}{(\sqrt{2} - 1)}$$

$$m = \sqrt{3}$$

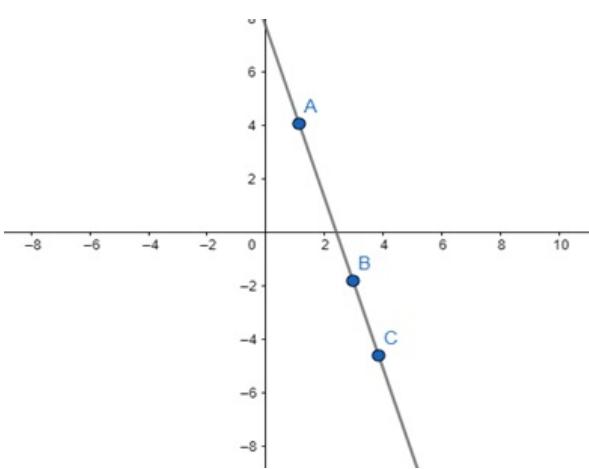

Now as we have $m = \tan\theta$

$$\tan\theta = \sqrt{3} \Rightarrow \theta = 60^\circ$$

So, angle line makes with the positive x - axis is 60° .

Question: 17

If two lines having the same slope pass through a common point, then two lines will coincide. Hence, if A, B and C are three points in the XY - plane, then they will lie on a line, i.e., three points are collinear if and only if slope of AB = slope of BC.

Slope of AB = slope of BC

$$\frac{-2 - 4}{3 - 1} = \frac{-5 - (-2)}{4 - 3} \Rightarrow \frac{-6}{2} = \frac{-3}{1}$$

$$-3 = -3$$

Hence verified, i.e. points are collinear. Now using two point form of the equation

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1) \text{ where } \frac{y_2 - y_1}{x_2 - x_1} = \text{slope of line}$$

$$y - 4 = -3(x - 1)$$

$$y - 4 + 3x - 3 = 0$$

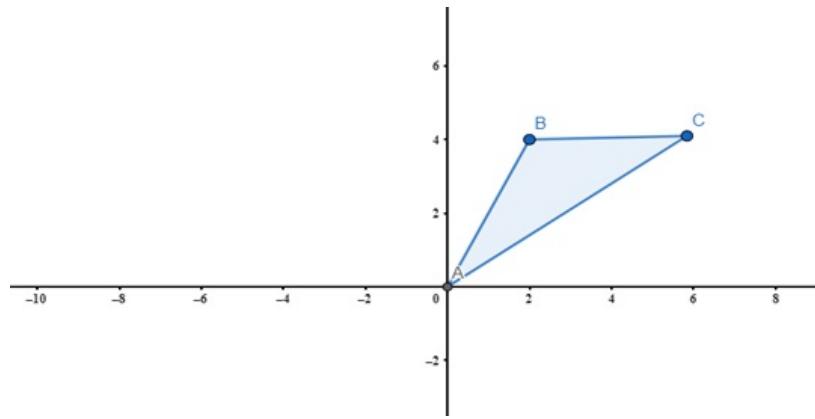

$$3x + y - 7 = 0$$

So, required equation of line is $3x + y - 7$.

Question: 18

For line AB,

$$m = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{4 - 0}{2 - 0} = \frac{4}{2}$$

$$m = 2$$

So, the equation of line AB is $y = 2x$.

For line AC,

$$m = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{4 - 0}{6 - 0} = \frac{4}{6}$$

$$m = \frac{2}{3}$$

Now using $y = mx$

$$y = \frac{2}{3}x \Rightarrow 2x - 3y = 0$$

So, the equation of line AC is $2x - 3y = 0$.

Now for line BC, the y coordinate of both is same means horizontal line (parallel to the x - axis) then the equation of line BC is given as

$$y = 4$$

So, the required equations of lines for AB: $y = 2x$

$$AC: 2x - 3y = 0$$

$$BC: y = 4$$

Question: 19

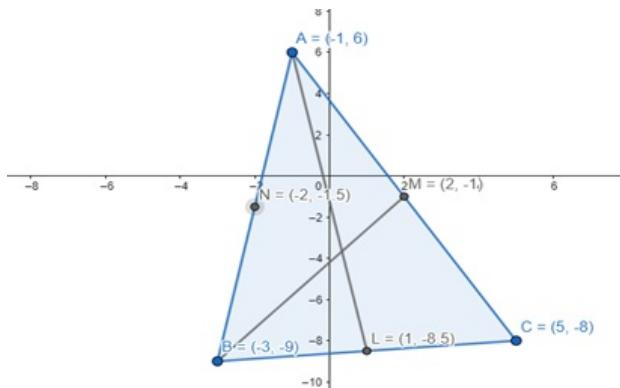

Now find the coordinate of L, M and N using mid - point theorem.

$$(x, y) = \left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2} \right)$$

$$\text{coordinates of } L = \left(\frac{-3 + 5}{2}, \frac{-9 + (-8)}{2} \right) \Rightarrow \left(1, \frac{-17}{2} \right)$$

$$\text{coordinates of } M = \left(\frac{-1 + 5}{2}, \frac{6 + (-8)}{2} \right) \Rightarrow (2, -1)$$

$$\text{coordinates of } N = \left(\frac{-1 + (-3)}{2}, \frac{6 + (-9)}{2} \right) \Rightarrow \left(-2, \frac{-3}{2} \right)$$

Now equation of medians AL, BM and CN using two point form

For median AL,

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1}(x - x_1)$$

$$y - 6 = \frac{\frac{-17}{2} - 6}{1 - (-1)}(x - (-1))$$

$$y - 6 = \frac{\frac{-17 - 12}{2}}{2}(x + 1) \Rightarrow y - 6 = \frac{-29}{4}(x + 1)$$

$$4(y - 6) = -29(x + 1)$$

$$4y - 24 + 29x + 29 = 0$$

$$29x + y + 5 = 0$$

For median BM,

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$$

$$y - (-9) = \frac{-1 - (-9)}{2 - (-3)} (x - (-3))$$

$$y + 9 = \frac{8}{5} (x + 3) \Rightarrow 5(y + 9) = 8(x + 3)$$

$$5y + 45 = 8x + 24$$

$$8x - 5y + 24 - 45 = 0$$

$$8x - 5y - 21 = 0$$

For median CN,

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$$

$$y - (-8) = \frac{\frac{-3}{2} - (-8)}{-2 - 5} (x - 5)$$

$$y + 8 = \frac{\frac{-3 + 16}{2}}{2} (x - 5) \Rightarrow y + 8 = \frac{13}{4} (x - 5)$$

$$4(y + 8) = 13(x - 5)$$

$$4y + 32 = 13x - 65$$

$$13x - 4y - 65 - 32 = 0$$

$$13x - 4y - 97 = 0$$

So, the required line of equations for medians are for AL: $29x + y + 5 = 0$

For BM: $8x - 5y - 21 = 0$

For CN: $13x - 4y - 97 = 0$

Question: 20

Find the equation

Solution:

Perpendicular bisector: A perpendicular bisector is a line segment which is perpendicular to the given line segment and passes through its mid-point (or we can say bisects the line segment).

Now to find the equation of perpendicular bisector first, we will find mid-point of the given line using mid-point formula (call it midpoint as M),

$$(x, y) = \left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2} \right)$$

$$\text{coordinates of } M = \left(\frac{10 + (-4)}{2}, \frac{4 + 9}{2} \right) \Rightarrow \left(3, \frac{13}{2} \right)$$

Now we will calculate the slope of the given line and since lines are perpendicular, so the slope of two is related as $m_1 \cdot m_2 = -1$.

$$\text{Slope of AB: } m_1 = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{9 - 4}{-4 - 10} = -\frac{5}{14}$$

Now the slope of perpendicular bisector is

$$m_1 \cdot m_2 = -1 \Rightarrow -\frac{5}{14} \cdot m_2 = -1$$

$$m_2 = \frac{14}{5}$$

Now equation of perpendicular bisector using two point form,

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$$

$$y - \frac{13}{2} = \frac{14}{5}(x - 3) \Rightarrow 5(2y - 13) = 28(x - 3)$$

$$10y - 65 = 28x - 84$$

$$28x - 10y - 84 + 65 = 0$$

$$28x - 10y - 19 = 0$$

So, required equation of perpendicular bisector $28x - 10y - 19 = 0$.

Question: 21

Find the equation

Solution:

Altitude: A line drawn from the vertex that meets the opposite side at right angles. It determines the height of the triangle.

In triangle ABC, let the altitudes from vertices A, B and C are AL, BM and CN on sides BC, AC and AB respectively.

Now we will find slope of sides and using the relation between the slopes of perpendicular lines i.e. $m_1 \cdot m_2 = -1$ we will find the slopes of altitudes.

$$\text{Slope of BC: } m_1 = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{0 - 1}{-1 - 1} = \frac{-1}{-2}$$

$$m_1 = \frac{1}{2}$$

$$\text{Slope of AC: } m_2 = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{0 - (-2)}{-1 - 2} = -\frac{2}{3}$$

$$\text{Slope of AB: } m_3 = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{1 - (-2)}{1 - 2} = -3$$

$$\text{Slope of AL: } m_1 \cdot m_1' = -1 \Rightarrow \frac{1}{2} \cdot m_1' = -1$$

$$m_1' = -2$$

$$\text{Slope of BM: } m_2 \cdot m_2' = -1 \Rightarrow \frac{-2}{3} \cdot m_2' = -1$$

$$m_2' = \frac{3}{2}$$

Slope of CN: $m_3 \cdot m_3' = -1 \Rightarrow -3 \cdot m_3' = -1$

$$m_3' = \frac{1}{3}$$

Now equation of altitudes using two point form

For altitude AL,

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$$

$$y - (-2) = -2(x - 2)$$

$$y + 2 + 2x - 4 = 0$$

$$2x + y - 2 = 0$$

For altitude BM,

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$$

$$y - 1 = -1(x - 1)$$

$$y - 1 + x - 1 = 0$$

$$x + y - 2 = 0$$

For altitude CN,

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$$

$$y - 0 = \frac{1}{3}(x - (-1))$$

$$3y = x + 1$$

$$x - 3y + 1 = 0$$

So, the required equations of altitudes are for AL: $2x + y - 2 = 0$

For BM: $x + y - 2 = 0$

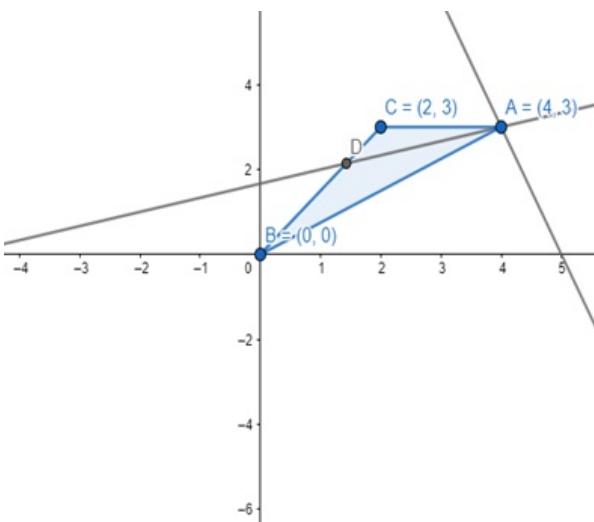

For CN: $x - 3y + 1 = 0$

Question: 22

If A(4, 3), B(0,

Solution:

Construction: Draw a line from vertex A intersecting side BC of the triangle at D (as there is one bisector for exterior angle also but it is the default that we have to find interior angle bisector).

As the angle between the sides AB and angle bisector AD and side AC and angle bisector AD is equal.

$$\angle A = 2\theta \Rightarrow \angle BAD = \angle CAD = \theta$$

Then using the angle between two lines, if the slope of AD be m and slope of AB

$$\text{Slope of AB} = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{3 - 0}{4 - 0} = \frac{3}{4}$$

Putting the values in the equation

$$\tan \theta = \frac{m_2 - m_1}{1 + m_1 \cdot m_2} \dots \dots \dots (1)$$

$$\Rightarrow \frac{\frac{3}{4} - m}{1 + m \cdot \frac{3}{4}} = \frac{\frac{3 - 4m}{4}}{\frac{4 + 3m}{4}}$$

$$\tan \theta = \frac{3 - 4m}{4 + 3m} \dots \dots \dots (2)$$

Again for side AC slope

$$\text{Slope of AC} = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{3 - 3}{2 - 4} = 0$$

Putting in equation (1)

$$\tan \theta = \frac{m_2 - m_1}{1 + m_1 \cdot m_2} \Rightarrow \frac{m - 0}{1 + 0 \cdot m} = m \dots \dots \dots (3)$$

From equation (2) and (3), we have

$$m = \frac{3 - 4m}{4 + 3m} \Rightarrow 4m + 3m^2 + 4m - 3 = 0$$

$$3m^2 + 8m - 3 = 0$$

From equation we have two values of $m - 3, \frac{1}{3}$

$\tan \theta = -3$ as $\tan x$ is negative in II and IV quadrant means it is obtuse angle either way (exterior here) we require interior angle so will consider the positive value of m .

$$m = \tan\theta = \frac{1}{3}$$

As we obtained the slope of angle bisector which passes through A vertex so using slope intercept form first calculate the value of the intercept

$$3 = \frac{1}{3}(4) + c \Rightarrow c = 3 - \frac{4}{3} \Rightarrow c = \frac{9-4}{3} \Rightarrow c = \frac{5}{3}$$

Putting the value of c in equation (4), we have

$$y = \frac{1}{3}x + \frac{5}{3} \Rightarrow x - 3y + 5 = 0$$

So, the required equation of angle bisector is $x - 3y + 5 = 0$.

Question: 23

the midpoints of

Solution:

Let us consider the coordinates of vertices of triangle A, B, C be (a, b) , (c, d) and (e, f) . Now using mid - point formula

$$(x, y) = \left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2} \right)$$

For side BC (midpoint D): $(2,1) = \frac{c+e}{2}, \frac{d+f}{2}$

$$\text{For side AC (midpoint E): } (-5, 7) = \frac{a + e}{2}, \frac{b + f}{2}$$

For side AB (midpoint F): $(-5, -5) = \frac{a + c}{2}, \frac{b + d}{2}$

Now from above equations, we have

$$c + e = 4, d + f = 2 \text{ (i)}$$

$$a + e = -10, b + f = 14 \text{ (ii)}$$

$$a + c = -10, b + d = -10 \text{ (iii)}$$

From subtract (i) from (ii), we get

$$a - c = -14, b - d = 12 \text{ (iv)}$$

Adding (iii) and (iv)

$$2a = -24 \Rightarrow a = -12, 2b = 2 \Rightarrow b = 1$$

Putting values of a, b in equation (iii)

$$c = -10 - (-12) \Rightarrow c = 2, d = -10 - 1 \Rightarrow d = -11$$

Again putting values in (i)

$$e = 4 - 2 \Rightarrow e = 2, f = 2 - (-11) \Rightarrow f = 13$$

So coordinates of A (-12,1), B(2,-11) and C(2,13).

Using two point form of the equation

Equation of side AB:

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$$

$$y - 1 = \frac{-11 - 1}{2 - (-12)} (x - (-12)) \Rightarrow y - 1 = \frac{-12}{14} (x + 12)$$

$$14(y - 1) = -12(x + 12)$$

$$14y - 14 + 12x + 144 = 0$$

$$12x + 14y + 130 = 0$$

$$6x + 7y + 65 = 0$$

Equation of side BC:

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$$

$$y - (-11) = \frac{13 - (-11)}{2 - 2} (x - 2) \Rightarrow y + 11 = \frac{24}{0} (x - 2)$$

$y = -11$ (slope is not defined i.e. line is vertical)

Equation of side CA:

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$$

$$y - 13 = \frac{1 - 13}{-12 - 2} (x - 2) \Rightarrow y - 13 = \frac{-12}{-14} (x - 2)$$

$$14(y - 13) = 12(x - 2)$$

$$12x - 24 - 14y + 182 = 0$$

$$12x - 14y + 158 = 0$$

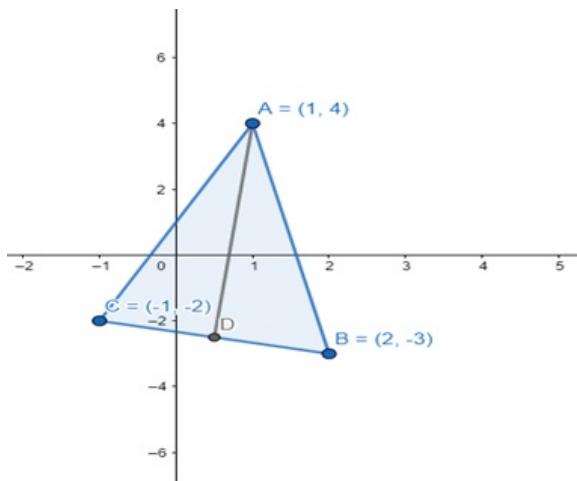

$$6x - 7y + 79 = 0$$

So, the required equations of sides for AB: $6x + 7y + 65 = 0$

For BC: $y = -11$

For CA: $6x - 7y + 79 = 0$

Question: 24

(i) Equation of median AD, we will find the midpoint of side BC

$$\text{For side BC (midpoint D): } (x, y) = \frac{2 + (-1)}{2}, \frac{-3 + (-2)}{2}$$

$$(x, y) = \left(\frac{1}{2}, \frac{-5}{2} \right)$$

Now using two point form of the equation of the line, we have

Equation of side AD:

$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$$

$$y - 4 = \frac{\frac{-5}{2} - 4}{\frac{1}{2} - 1} (x - 1) \Rightarrow y - 4 = \frac{\frac{-5 - 8}{2}}{\frac{1 - 2}{2}} (x - 1)$$

$$y - 4 = \frac{-13}{-1}(x - 1) \Rightarrow y - 4 = 13x - 13$$

$$13x - y - 13 + 4 = 0$$

$$13x - y - 9 = 0$$

So, required equation of altitude is $3x - y - 9 = 0$.

(ii) For the equation of altitude, we will need slope as we have a point through which line passes (A).

Now we will find the slope of side BC and using the relation between the slopes of perpendicular lines, i.e. $m_1 \cdot m_2 = -1$ we will find the slopes of altitude.

$$\text{Slope of BC: } m_1 = \frac{y_2 - y_1}{x_2 - x_1} \Rightarrow \frac{-2 + (-3)}{-1 - 2} = \frac{-5}{-3}$$

$$m_1 = \frac{5}{3}$$

$$\text{Slope of AM : } m_1 \cdot m_1' = -1 \Rightarrow \frac{5}{3} \cdot m_1' = -1$$

$$m_1 = \frac{-3}{5}$$

Using slope intercept form, we will first calculate intercept.

$$4 = \frac{-3}{5}(1) + c \Rightarrow c = 4 + \frac{3}{5}$$

$$c = \frac{20 + 3}{5} \Rightarrow c = \frac{23}{5}$$

Putting in equation (1)

$$y = \frac{-3}{5}x + \frac{23}{5} \Rightarrow 3x + 5y - 23 = 0$$

So, required equation of altitude is $3x + 5y - 23 = 0$.

(iii) We have a slope of perpendicular and a mid point from the previous solution

$$m_1 = \frac{-3}{5}, \text{ midpoint of BC}(\text{point D}) (x, y) = \left(\frac{1}{2}, \frac{-5}{2} \right)$$

Now for perpendicular bisector, it passes through the midpoint of BC, i.e. we have a slope of the equation and a point through which it passes so we can use the slope - intercept form and calculate intercept,

$$y = mx + c \dots\dots\dots\dots\dots (i)$$

$$\frac{-5}{2} = \frac{-3}{5} \left(\frac{1}{2} \right) + c \Rightarrow c = \frac{-5}{2} + \frac{3}{10}$$

$$c = \frac{-25 + 3}{10} \Rightarrow c = \frac{-22}{10}$$

$$c = \frac{-11}{5}$$

Putting in equation (i) value of c,

$$y = \frac{-3}{5}x + \frac{-11}{5} \Rightarrow 3x + y + 11 = 0$$

So, the required equation of perpendicular bisector is $3x + y + 11 = 0$.

Exercise : 20D

Question: 1

Find the equation

Solution:

(i) Formula to be used: $y = mx + c$ where m is the slope of the line and c is the y - intercept.

Here, $m = 3$ and $c = 5$.

Hence, $y = (3)x + (5)$

i.e. $y = 3x + 5$

(ii) Formula to be used: $y = mx + c$ where m is the slope of the line and c is the y - intercept.

Here, $m = -1$ and $c = 4$.

Hence, $y = (-1)x + (4)$

i.e. $x + y = 4$

(iii) Formula to be used: $y = mx + c$ where m is the slope of the line and c is the y - intercept.

Here, $m = -\frac{2}{5}$ and $c = -3$.

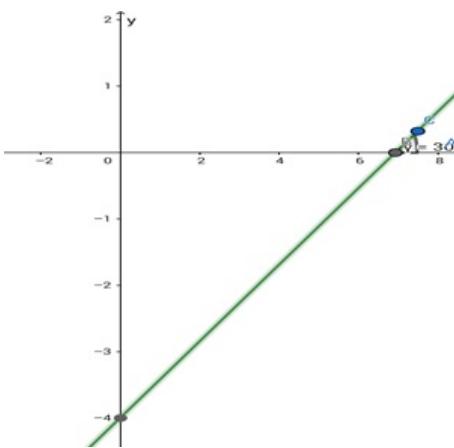

Hence, $y = \left(-\frac{2}{5}\right)x + (-3)$

Or, $5y = -2x - 3$ i.e. $2x + 5y + 3 = 0$

Question: 2

Find the equation

Solution:

Given : The given line makes an angle of 30° with the x - axis. The y - intercept = - 4.

So, the slope of the line is $m = \tan\theta = \tan 30^\circ = \frac{1}{\sqrt{3}}$.

Formula to be used: $y = mx + c$ where m is the slope of the line and c is the y - intercept.

The equation of the line is $y = \frac{1}{\sqrt{3}}x - 4$

Or, $\sqrt{3}y = x - 4\sqrt{3}$ i.e. $x - \sqrt{3}y = 4\sqrt{3}$

Question: 3

Find the equation

Solution:

Given:

$$\theta = \frac{5\pi}{6}$$

\therefore slope, $m = \tan\theta = \tan \frac{5\pi}{6} = -\frac{1}{\sqrt{3}}$

The y - intercept is 6 units.

Formula to be used: $y = mx + c$ where m is the slope of the line and c is the y - intercept.

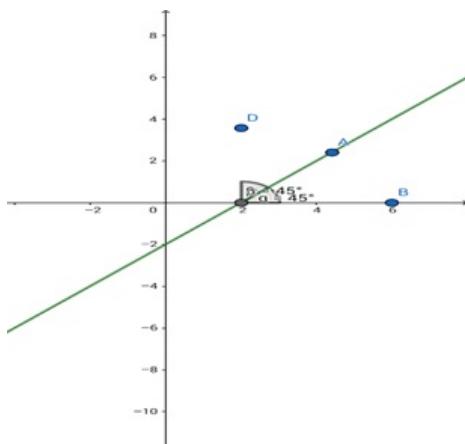

The equation of the line is $y = -\frac{1}{\sqrt{3}}x + 6$

i.e. $\sqrt{3}y + x - 6\sqrt{3} = 0$

Question: 4

Find the equation

Solution:

Given: The line is equally inclined to both the axes.

The angle between the coordinate axes = 90°

If the inclination to both the axes is θ then $\theta + \theta = 90^\circ$

i.e. $\theta = 45^\circ$

∴ slope of the line, $m = \tan \theta = \tan 45^\circ = 1$

The y - intercept = - 2 units

Formula to be used: $y = mx + c$ where m is the slope of the line and c is the y - intercept.

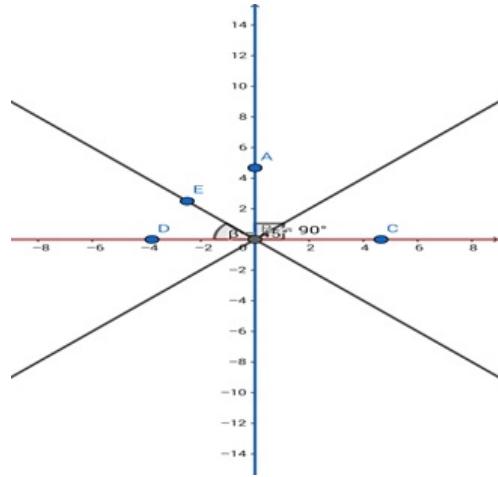

The equation of the line is $y = 1 \cdot x + (-2) = x - 2$

i.e. $x - y = 2$

Question: 5

Find the equation

Solution:

Given: The straight lines are $x = 0$ and $y = 0$.

Formula to be used: If θ is the angle between two straight lines $a_1x + b_1y + c_1 = 0$ and $a_2x + b_2y$

+ $c_2 = 0$ then the equation of their angle bisector is
$$\left| \frac{a_1x + b_1y + c_1}{\sqrt{a_1^2 + b_1^2}} \right| = \left| \frac{a_2x + b_2y + c_2}{\sqrt{a_2^2 + b_2^2}} \right|$$

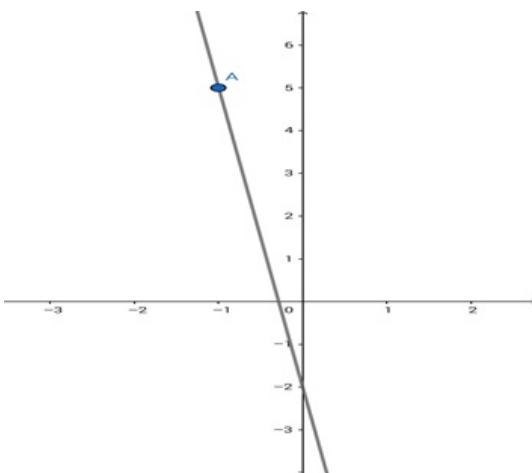

∴ the equation of the angle bisectors is
$$\left| \frac{x}{\sqrt{1^2}} \right| = \left| \frac{y}{\sqrt{1^2}} \right|$$

i.e. $x = \pm y$

Question: 6

Find the equation

Solution:

Given: The y - intercept = - 2.

The line passes through (- 1,5).

Formula to be used: $y = mx + c$ where m is the slope of the line and c is the y - intercept.

The equation of the line is $y = mx + (- 2) = mx - 2$.

Now, this line passes through (- 1,5).

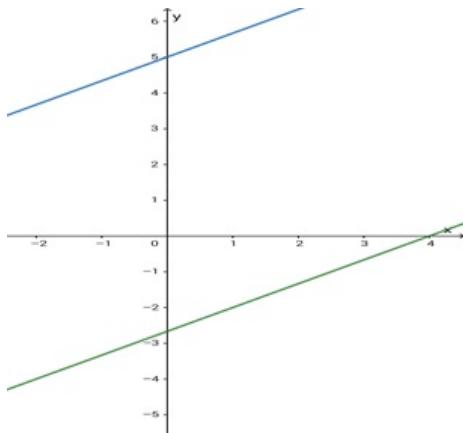

$$\therefore 5 = m(-1) - 2 = -m - 2 \text{ i.e. } m = -(5 + 2) = -7$$

$$\therefore y = (-7)x + (-2) = -7x - 2 \text{ i.e. } 7x + y + 2 = 0$$

Question: 7

Find the equation

Solution:

Given: The given line is $2x - 3y = 8$. The line parallel to this line has a y - intercept of 5units.

Formula to be used: If $ax + by = c$ is a straight line then the line parallel to the given line is of the form $ax + by = d$, where a,b,c,d are arbitrary real constants.

A line parallel to the given line has a slope of $\frac{2}{3}$ and is of the form $2x - 3y = k$, where k is any arbitrary real constant.

Now, $2x - 3y = k$

or, $3y = 2x - k$

$$\text{or, } y = \left(\frac{2}{3}\right)x + \left(-\frac{k}{3}\right)$$

which is of the form $y = mx + c$, where c is the y - intercept.

$$\therefore c = -\frac{k}{3} = 5$$

So, $k = (-3)x5 = -15$

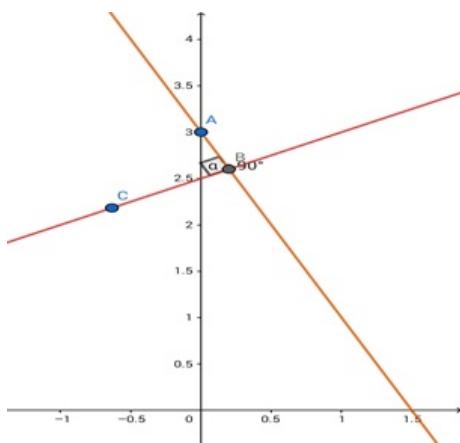

Equation of the required line is $2x - 3y = -15$

i.e. $2x - 3y + 15 = 0$

Question: 8

Find the equation

Solution:

Given: The given line is $x - 2y + 5 = 0$. The line perpendicular to this given line passes through $(0, 3)$

Formula to be used: The product of slopes of two perpendicular lines = - 1.

The slope of this line is $1/2$.

$$\therefore \text{the slope of the perpendicular line} = \frac{-1}{1/2} = -2.$$

The equation of the line can be written in the form $y = (-2)x + c$

(c is the y - intercept)

This line passes through $(0, 3)$ so the point will satisfy the equation of the line.

$$\therefore 3 = (-2)x0 + c \text{ i.e. } c = 3$$

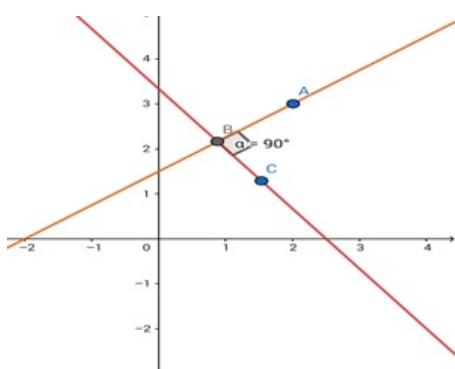

The required equation is $y = -2x + 3$

i.e. $2x + y = 3$

Question: 9

Find the equation

Solution:

Given: The given line is $4x + 3y = 10$. The line perpendicular to this line passes through $(2, 3)$.

Formula to be used: The product of slopes of two perpendicular lines = - 1

Slope of this line is $-\frac{4}{3}$.

$$\therefore \text{the slope of the perpendicular line} = \frac{-1}{\frac{-4}{3}} = \frac{3}{4}$$

The equation of the line can be written in the form $y = \left(\frac{3}{4}\right)x + c$

(c is the y - intercept)

This line passes through (2,3), so the point will satisfy the equation of the line.

$$\therefore 3 = \left(\frac{3}{4}\right)x_2 + c \text{ i.e. } c = 3 - \frac{3}{2} = \frac{3}{2}$$

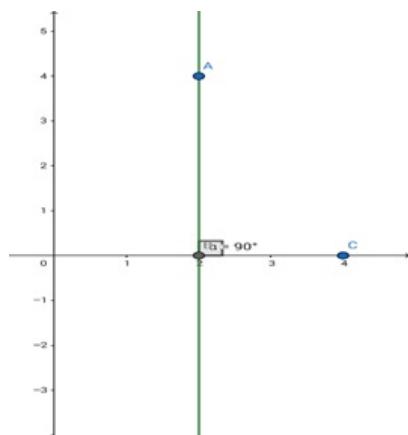

The required equation is $y = \frac{3}{4}x + \frac{3}{2}$

or, $4y = 3x + 6$ i.e. $3x - 4y + 6 = 0$.

Question: 10

Find the equation

Solution:

Given: The line is perpendicular to x - axis and passes through (2,4)

The equation of the line perpendicular to the x - axis ($y = 0$) can be represented as $x = c$, where c is a real constant.

Now, this line passes through (2,4).

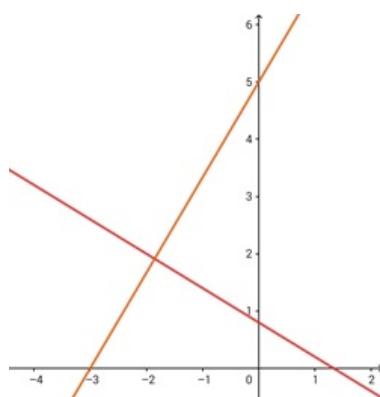

$$\therefore c = 2$$

The required equation is $x = 2$

Question: 11

Find the equation

Solution:

Given: The given line is $3x + 5y = 4$. The perpendicular line has an x - intercept of - 3.

Formula to be used: The product of slopes of two perpendicular lines = - 1.

The slope of this line is $-3/5$.

$$\therefore \text{the slope of the perpendicular line} = \frac{-1}{-\frac{3}{5}} = \frac{5}{3}.$$

The equation of the line can be written in the form $y = \left(\frac{5}{3}\right)x + c$

(c is the y - intercept)

This line intercepts the x - axis when $y = 0$.

$$\text{So, the x - intercept: } 0 = \left(\frac{5}{3}\right)x + c \text{ i.e. } x = -\frac{3c}{5}$$

Now, it is given that the x - intercept is - 3.

$$\therefore -\frac{3c}{5} = -3 \text{ i.e. } c = 5$$

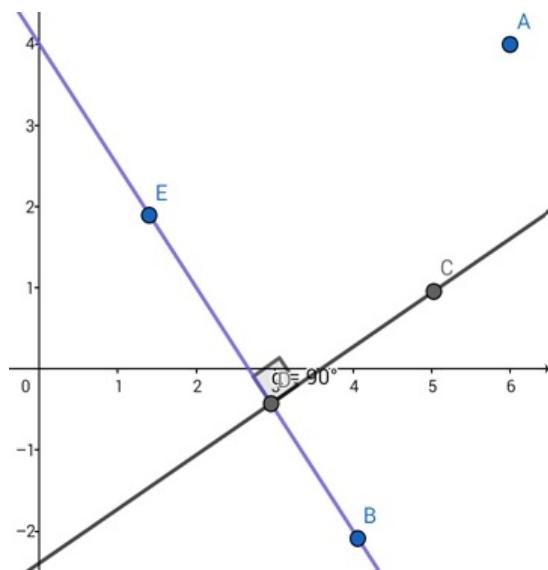

The required equation of the line is $y = \left(\frac{5}{3}\right)x + 5$

$$\text{i.e. } 5x - 3y + 15 = 0$$

Question: 12

Find the equation

Solution:

Given: The given line is $3x + 2y = 8$. The perpendicular line passes through the midpoint of (6,4) and (4, -2).

Formulae to be used: The product of slopes of two perpendicular lines = - 1.

If (a,b) and (c,d) be two points, then their midpoint is given by $\left(\frac{a+c}{2}, \frac{b+d}{2}\right)$

The slope of this line is $-3/2$.

$$\therefore \text{the slope of the perpendicular line} = \frac{-1}{-\frac{3}{2}} = \frac{2}{3}.$$

The equation of the line can be written in the form $y = \left(\frac{2}{3}\right)x + c$

(c is the y - intercept)

This line passes through the midpoint of (6,4) and (4, -2).

The co - ordinates of the midpoint of the line joining the given points is $\left(\frac{6+4}{2}, \frac{4+(-2)}{2}\right) = (5,1)$

(5,1) satisfies the equation $y = \left(\frac{2}{3}\right)x + c$

$$\therefore 1 = \left(\frac{2}{3}\right)x5 + c \text{ or, } c = 1 - \frac{10}{3} = -\frac{7}{3}$$

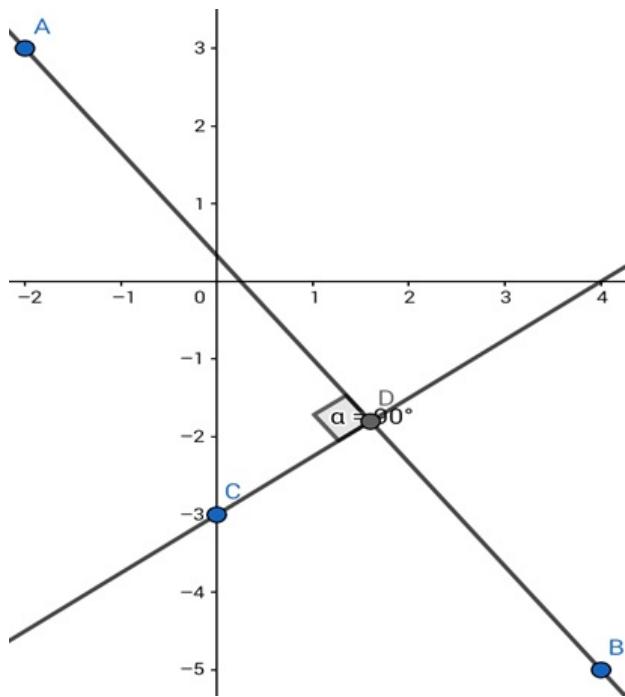

The required equation is $y = \left(\frac{2}{3}\right)x + \left(-\frac{7}{3}\right)$

i.e. $2x - 3y = 7$

Question: 13

Find the equation

Solution:

Given: The line perpendicular to the line passing through $(-2, 3)$ and $(4, -5)$ has the y -intercept of -3 .

Formula to be used: If (a,b) and (c,d) are two points then the equation of the line passing through them is $\frac{y-d}{x-c} = \frac{d-b}{c-a}$

Product of slopes of two perpendicular lines = -1

The equation of the line joining points $(-2, 3)$ and $(4, -5)$ is

$$\frac{y - (-5)}{x - 4} = \frac{(-5) - 3}{4 - (-2)}$$

$$\text{or, } \frac{y + 5}{x - 4} = \frac{-8}{6} = -\frac{4}{3}$$

$$\text{or, } 3y + 15 = -4x + 16 \text{ or, } 4x + 3y = 1$$

Slope of this line is $-\frac{4}{3}$.

$$\therefore \text{the slope of the perpendicular line} = \frac{-1}{-\frac{4}{3}} = \frac{3}{4}$$

The equation of the line can be written in the form $y = \left(\frac{3}{4}\right)x + c$

(c is the y -intercept)

But, the y -intercept is -3 .

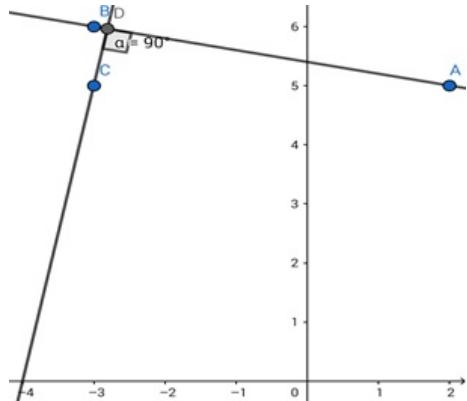

The required line is $y = \frac{3}{4}x + (-3)$

i.e. $3x - 4y = 12$

Question: 14

Find the equation

Solution:

Given: The line perpendicular to the line passing through (2,5) and (-3,6) passes through (-3,5).

Formula to be used: If (a,b) and (c,d) are two points then the equation of the line passing through them is $\frac{y-b}{x-a} = \frac{d-b}{c-a}$

Product of slopes of two perpendicular lines = -1

The equation of the line joining points (2,5) and (-3,6) is

$$\frac{y-5}{x-2} = \frac{5-6}{2-(-3)}$$

$$\text{or, } \frac{y-5}{x-2} = \frac{-1}{5}$$

$$\text{Or, } 5y - 25 = -x + 2$$

i.e. the given line is $x + 5y = 27$.

The slope of this line is $-1/5$.

∴ the slope of the perpendicular line = $\frac{-1}{-1/5} = 5$.

The equation of the line can be written in the form $y = 5x + c$.

(c is the y - intercept)

This line passes through (-3,5).

Hence, $5 = 5(-3) + c$ or, $c = 20$

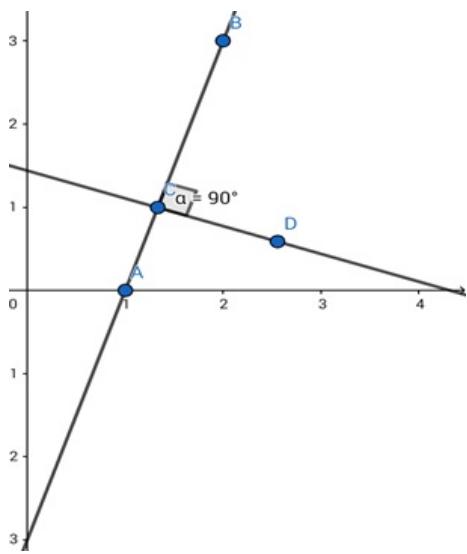

The required equation of the line will be $y = 5x + 20$

i.e. $5x - y + 20 = 0$

Question: 15

A line perpendicu

Solution:

Given: A line perpendicular to the line segment joining the points (1, 0) and (2, 3) divides it in the ratio 1 : 2.

Formula to be used: If (a,b) and (c,d) are two points then the equation of the line passing through them is $\frac{y-b}{x-a} = \frac{d-b}{c-a}$

If (a_1, b_1) and (a_2, b_2) be two points , then the co - ordinates of the point dividing their join in the ratio a:b is given by

$$x - \text{co ordinate} = \left(\frac{a_1 X_b + a_2 X_a}{a + b} \right)$$

$$y - \text{co ordinate} = \left(\frac{b_1 X_b + b_2 X_a}{a + b} \right)$$

The equation of the line joining points (1,0) and (2,3) is

$$\frac{y-0}{x-1} = \frac{0-3}{1-2}$$

$$\text{or}, \frac{y}{x-1} = \frac{-3}{-1} = 3$$

$$\text{or}, y = 3x - 3 \text{ or}, 3x - y = 3$$

i.e. the given line is $3x - y = 3$.

Accordingly, the required co - ordinates of the point dividing the join of (1,0) and (2,3) in the ratio 1:2 are

$$\left(\left(\frac{1X2 + 2X1}{1+2} \right), \left(\frac{0X2 + 3X1}{1+2} \right) \right) = \left(\frac{4}{3}, 1 \right)$$

The given line is $3x - y = 3$.

The slope of this line is 3.

$$\therefore \text{the slope of the perpendicular line} = \frac{-1}{3} = -\frac{1}{3}$$

The equation of the line can be written in the form $y = -\frac{1}{3}x + c$

(c is the y - intercept)

This line will pass through $(\frac{4}{3}, 1)$.

$$\therefore 1 = -\frac{1}{3}X\frac{4}{3} + c \text{ or}, c = 1 + \frac{4}{9} = \frac{13}{9}$$

The required equation is $y = -\frac{1}{3}x + \frac{13}{9}$

i.e. $3x + 9y = 13$

Exercise : 20E

Question: 1

Find the equation

Solution:

To Find: The equation of a line with intercepts -3 and 5 on the x-axis and y-axis respectively.

Given :Let a and b be the intercepts on x-axis and y-axis respectively.

Then, the x-intercept is $a = -3$

y-intercept is $b = 5$

Formula used:

we know that intercept form of a line is given by:

$$\frac{x}{a} + \frac{y}{b} = 1$$

$$\frac{x}{-3} + \frac{y}{5} = 1$$

$$5x - 3y = -15$$

$$5x - 3y + 15 = 0$$

Hence $5x - 3y + 15 = 0$ is the required equation of the given line.

Question: 2

Find the equation

Solution:

To Find:The equation of the line with intercepts 4 and -6 on the x-axis and y-axis respectively.

Given : Let a and b be the intercepts on x-axis and y-axis respectively.

Then,x-intercept be $a = 4$

y-intercept be $b = -6$

Formula used:

we know that intercept form of a line is given by:

$$\frac{x}{a} + \frac{y}{b} = 1$$

$$\frac{x}{4} + \frac{y}{-6} = 1$$

$$-3x + 2y = -12$$

$$3x - 2y - 12 = 0$$

Hence $3x - 2y - 12 = 0$ is the required equation of the given line.

Question: 3

Find the equation

Solution:

To Find: The equation of the line with equal intercepts on the coordinate axes and that passes through the point (4,7).

Given : Let a and b be two intercepts of x-axis and y-axis respectively.

Also,given that two intercepts are equal, i.e., $a=b$

And (4, 7) passes through the point (x, y)

Formula used:

Now since intercept form of a line is given:

$$\frac{x}{a} + \frac{y}{b} = 1$$

$$\frac{4}{a} + \frac{7}{b} = 1$$

$$\frac{4+7}{a} = 1$$

$$a = 11 = b$$

Therefore, The required Equation of the line is $\frac{x}{11} + \frac{y}{11} = 1$

$$\Rightarrow x + y = 11$$

Question: 4

To Find: The equation of the line passing through (3, -5) and cuts off intercepts on the axes which are equal in magnitude but opposite in sign.

Given : Let a and b be two intercepts of x-axis and y-axis respectively.

According to the question $a = -b$ or $b = -a$

And (3 , -5) passes through the point (x, y), thus satisfies the equation

Formula used:

Now since intercept form of the line is given by , $\frac{x}{a} + \frac{y}{b} = 1$

$$\frac{3}{a} + \frac{-5}{-a} = 1$$

$$\frac{3+5}{a} = 1$$

$$a = 8 \text{ and } b = -8$$

Equation of the line is $\frac{x}{8} + \frac{y}{-8} = 1$

\Rightarrow Hence ,the required equation of the line is $\frac{x}{8} - \frac{y}{8} = 1 \Rightarrow x - y = 8$

Question: 5

Find the equation

Solution:

To Find: The equation of the line passing through the point (2, 2) and cutting off intercepts on the axes, whose sum is 9.

Given : Let a and b be two intercepts of x-axis and y-axis respectively.

sum of the intercepts is 9, i.e., $a+b = 9$

$$\Rightarrow a = 9 - b \text{ or } b = 9 - a$$

Formula used:

The equation of a line is given by:

$$\frac{x}{a} + \frac{y}{b} = 1$$

The given point (2, 2) passing through the line and satisfies the equation of the line.

$$\frac{2}{a} + \frac{2}{9-a} = 1$$

$$2(9-a) + 2a = 9a - a^2$$

$$18 - 2a + 2a = 9a - a^2$$

$$a^2 - 9a + 18 = 0$$

$$a^2 - 6a - 3a + 18 = 0$$

$$a(a-6) - 3(a-6) = 0$$

$$(a-3)(a-6) = 0$$

$$a = 3, a = 6$$

when $a = 3, b=6$ and $a=6, b=3$

case 1 : when $a=3$ and $b=6$

Equation of the line : $\frac{x}{a} + \frac{y}{b} = 1$

$$\frac{x}{3} + \frac{y}{6} = 1$$

Hence, $2x + y = 6$ is the required equation of the line.

case 2 : when $a=6$ and $b=3$

Equation of the line : $\frac{x}{a} + \frac{y}{b} = 1$

$$\frac{x}{6} + \frac{y}{3} = 1$$

Hence, $x + 2y = 6$ is the required equation of the line.

Therefore, $2x + y = 6$ is the required equation of the line when $a=3$ and $b=6$. And, $x + 2y = 6$ is the required equation of the line when $a=6$ and $b=3$.

Question: 6

Find the equation

Solution:

To Find: The equation of the line that passes through the point (22, -6) and intercepts on the x-axis exceeds the intercept on the y-axis by 5.

Given : let x-intercept be a and y-intercept be b .

According to the question : $a = b + 5$

Formula used:

And the given point satisfies the equation of the line, so

$$\frac{x}{a} + \frac{y}{b} = 1$$

$$\frac{22}{b+5} + \frac{-6}{b} = 1$$

$$22b - 6b - 30 = b^2 + 5b$$

$$11b - 30 = b^2$$

$$b^2 - 11b + 30 = 0$$

$$b(b-6) - 5(b-6) = 0$$

$$(b-5)(b-6) = 0$$

The values are $b=5, b=6$

When $b=5$ then $a=10$

and $b=6$ then $a=11$

case 1 : when $b=5$ and $a=10$

$$\text{Equation of the line : } \frac{x}{a} + \frac{y}{b} = 1$$

$$\frac{x}{10} + \frac{y}{5} = 1$$

$$\frac{x+2y}{10} = 1$$

Hence, $x + 2y = 10$ is the required equation of the line.

case 2 : when $b=6$ and $a=11$

$$\text{Equation of the line : } \frac{x}{a} + \frac{y}{b} = 1$$

$$\frac{x}{11} + \frac{y}{6} = 1$$

$$\frac{6x+11y}{66} = 1$$

Hence, $6x + 11y = 66$ is the required equation of the line.

Therefore, $x + 2y = 10$ is the required equation of the line when $b=5$ and $a=10$. And $6x + 11y = 66$ is the required equation of the line when $b=6$ and $a=11$.

Question: 7

Find the equation

Solution:

To Find: The equation of the line whose portion intercepted between the axes is bisected at the point $(3, -2)$.

Formula used:

Let the equation of the line be

$$\frac{x}{a} + \frac{y}{b} = 1$$

Since it is given that this equation , whose portion is intercepted between the axes is bisected i.e.; is divided into ratio 1:1 .

Let A(a,0) and B(0,b) be the points foring the coordinate axis.

\Rightarrow a and b are intercepts of x and y-axis respectively.

By using mid-point formula (m:n = 1:1)

$$(x, y) = \left(\frac{y_1 + x_1}{2}, \frac{y_2 + x_2}{2} \right) = \left(\frac{a}{2}, \frac{b}{2} \right)$$

Since given point (3 , -2) divides coordinate axis in 1:1 ratio

$$(x , y) = (3 , -2)$$

$$\Rightarrow \frac{a}{2} = 3 \text{ and } \frac{b}{2} = -2$$

$$a=6 \text{ } b=-4$$

$$\text{equation of the line : } \frac{x}{a} + \frac{y}{b} = 1$$

$$\frac{x}{6} + \frac{y}{-4} = 1$$

$$-4x + 6y = -24$$

$$-2x + 3y = -12$$

Hence the required equation of the line is $2x - 3y = 12$.

Question: 8

Find the equation

Solution:

To Find: The equation of the line whose portion intercepted between the coordinate axes is divided at the point (5, 6) in the ratio 3 : 1.

Given : The coordinate axes is divided in the ratio 3 : 1

$$(x_1 , y_1) = A(a,0)$$

$$(x_2 , y_2) = B(0, b)$$

Where a and b are intercepts of the line.

Formula used:

$$\text{The equation of the line is : } \frac{x}{a} + \frac{y}{b} = 1$$

And the co-ordinate axis is divided at (5,6) , thus by using Section formula

$$(x , y) = \left(\frac{my_1 + nx_1}{m+n}, \frac{my_2 + nx_2}{m+n} \right)$$

$$= \left(\frac{3*0+a}{4}, \frac{3b}{4} \right) = \left(\frac{a}{4}, \frac{3b}{4} \right)$$

(5,6) divides the co-ordinate axis, thus $(x,y)= (5,6)$.

$$\frac{a}{4} = 5 \Rightarrow a = 20 , \frac{3b}{4} = 6 \Rightarrow b = 8$$

Equation of the line becomes $\frac{x}{20} + \frac{y}{8} = 1$

$$8x + 20y = 160$$

$$2x + 5y = 40$$

Hence the required equation of the line is $2x + 5y = 40$.

Question: 9

A straight line p

Solution:

Given : The ratio of the line intercepted between the axes is 2 :3

$$\text{Let } (x_1, y_1) = A(a, 0)$$

$$\text{And } (x_2, y_2) = B(0, b)$$

Where a and b are intercepts of the line.

Formula used:

The equation of the line is : $\frac{x}{a} + \frac{y}{b} = 1$

And the co-ordinate axis is divided at (5,-2) , thus by using Section formula

$$(x, y) = \left(\frac{my_1 + nx_1}{m+n}, \frac{my_2 + nx_2}{m+n} \right)$$
$$= \left(\frac{2*0 + 3a}{5}, \frac{2b + 3*0}{5} \right) = \left(\frac{3a}{5}, \frac{2b}{5} \right)$$

(5,-2) divides the co-ordinate axis, thus $(x,y)= (5,-2)$.

$$\frac{3a}{5} = 5 \Rightarrow a = 25/3, \frac{2b}{5} = -2 \Rightarrow b = -5$$

Equation of the line becomes $\frac{x}{a} + \frac{y}{b} = 1$

$$\frac{x}{25/3} + \frac{y}{-5} = 1$$

$$\frac{3x}{25} - \frac{y}{5} = 1$$

$$\frac{3x - 5y}{25} = 1$$

Hence , $3x - 5y = 25$ is the required equation of the line.

Question: 10

If the straight l

Solution:

To Find: The values of a and b when the line $\frac{x}{a} + \frac{y}{b} = 1$ passes through the points (8, -9) and (12, -15).

Given : the equation of the line : $\frac{x}{a} + \frac{y}{b} = 1$ equation 1

Also (8, -9) passes through equation 1

$$\frac{8}{a} - \frac{9}{b} = 1$$

$$8b - 9a = ab \text{ equation 2}$$

And (12, -15) passes through equation 1

$$\frac{12}{a} - \frac{15}{b} = 1$$

$$12b - 15a = ab \text{ equation 3}$$

Solving equation 2 and 3

$$a = 2.$$

Put a=2 in equation 2

$$8b - 9a = ab$$

$$8b - 18 = 2b$$

$$6b = 18 \Rightarrow b = 3$$

Hence the values of a and b are 2 and 3 respectively.

Exercise : 20F

Question: 1 A

Find the equation

Solution:

To Find: The equation of the line.

Given: $p = 3$ and $\alpha = 450$

Here p is the perpendicular that makes an angle α with positive direction of x-axis , hence the equation of the straight line is given by:

Formula used:

$$x \cos \alpha + y \sin \alpha = p$$

$$x \cos 450 + y \sin 450 = 3$$

$$\text{i.e;} \cos 450 = \cos (360 + 90) = \cos 90 [\because \cos(360 + x) = \cos x]$$

$$\text{similarly, } \sin 450 = \sin (360 + 90) = \sin 90 [\because \sin(360 + x) = \sin x]$$

$$\text{hence, } x \cos 90 + y \sin 90 = 3$$

$$x \times 0 + y \times 1 = 3$$

Hence the required equation of the line is $y = 3$.

Question: 1 B

Find the equation

Solution:

Given: $p = 5$ and $\alpha = 1350$

Here p is the perpendicular that makes an angle α with positive direction of x-axis , hence the equation of the straight line is given by:

Formula used:

$$x \cos \alpha + y \sin \alpha = p$$

$$x \cos 1350 + y \sin 1350 = 5$$

$$\text{i.e;} \cos 1350 = \cos ((4 \times 360) - 90) = \cos((4 \times 2\pi) - 90) = \cos 90$$

$$\text{similarly, } \sin 1350 = \sin ((4 \times 360) - 90) = \sin((4 \times 2\pi) - 90) = -\sin 90$$

$$\text{hence, } x \cos 90 + y (-\sin 90) = 5$$

$$x \times (0) - y \times 1 = 5$$

Hence The required equation of the line is $y = -5$.

Question: 1 C

Find the equation

Solution:

$$\text{Given: } p = 8 \text{ and } \alpha = 1500$$

Here p is the perpendicular that makes an angle α with positive direction of x -axis , hence the equation of the straight line is given by:

Formula used:

$$x \cos \alpha + y \sin \alpha = p$$

$$x \cos 1500 + y \sin 1500 = 8$$

$$\text{i.e;} \cos 1500 = \cos ((4 \times 360) + 60) = \cos((4 \times 2\pi) + 60) = \cos 60$$

$$\text{similarly, } \sin 1500 = \sin ((4 \times 360) + 60) = \sin((4 \times 2\pi) + 60) = \sin 60$$

$$\text{hence, } x \cos 60 + y \sin 60 = 8$$

$$x \times (1/2) + y \times (\sqrt{3}/2) = 8$$

Hence The Required equation of the line is $x + \sqrt{3}y = 16$.

Question: 1 D

Find the equation

Solution:

$$\text{Given: } p = 3 \text{ and } \alpha = 2250$$

Here p is the perpendicular that makes an angle α with positive direction of x -axis , hence the equation of the straight line is given by:

Formula used:

$$x \cos \alpha + y \sin \alpha = p$$

$$x \cos 2250 + y \sin 2250 = 3$$

$$\text{i.e;} \cos 2250 = \cos ((6 \times 360) + 90) = \cos((6 \times 2\pi) + 90) = \cos 90$$

$$\text{similarly, } \sin 2250 = \sin ((6 \times 360) + 90) = \sin((6 \times 2\pi) + 90) = \sin 90$$

$$\text{hence, } x \cos 90 + y \sin 90 = 3$$

$$x \times (0) + y \times 1 = 3$$

Hence The required equation of the line is $y = 3$.

Question: 1 E

Find the equation

Solution:

$$\text{Given: } p = 2 \text{ and } \alpha = 3000$$

Here p is the perpendicular that makes an angle α with positive direction of x -axis , hence the

equation of the straight line is given by:

Formula used:

$$x \cos \alpha + y \sin \alpha = p$$

$$x \cos 3000 + y \sin 3000 = 2$$

$$\text{i.e;} \cos 3000 = \cos((8 \times 360) + 120) = \cos((8 \times 2\pi) + 120) = \cos 120 = \cos(180 - 60) = \cos 60$$

$$\text{similarly, } \sin 3000 = \sin((8 \times 360) + 120) = \sin((8 \times 2\pi) + 120) = \sin 120$$

$$= \sin(180 - 60) = -\sin 60$$

$$\text{hence, } x \cos 60 + y (-\sin 60) = 2$$

$$x \times (1/2) - y \times (\sqrt{3}/2) = 2$$

Hence The required equation of the line is $x - \sqrt{3}y = 4$

Question: 1 F

Find the equation

Solution:

$$\text{Given: } p = 4 \text{ and } \alpha = 1800$$

Here p is the perpendicular that makes an angle α with positive direction of x -axis , hence the equation of the straight line is given by:

Formula used:

$$x \cos \alpha + y \sin \alpha = p$$

$$x \cos 1800 + y \sin 1800 = 4$$

$$\text{i.e;} \cos 1800 = \cos(5 \times 360) = \cos(5 \times 2\pi) = \cos 360 = 1$$

$$\text{similarly, } \sin 1800 = \sin(5 \times 360) = \sin(5 \times 2\pi) = \sin 360 = 0$$

$$\text{hence, } x \times 1 + y \times 0 = 4$$

Hence The required equation of the line is $x=4$.

Question: 2

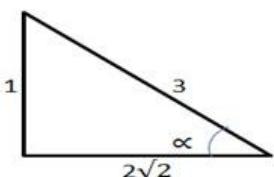

The length of the

Solution:

To Find: The equation of the line .

$$\text{Given : } p=2 \text{ units and } \sin \alpha = \frac{1}{3}$$

$$\text{Since } \sin \alpha = \frac{\text{opp}}{\text{hyp}} = \frac{1}{3}$$

Using Pythagoras theorem :

$$\text{adj} = \sqrt{9-1} = \sqrt{8} = 2\sqrt{2} \text{ units.}$$

$$\text{i.e;} \cos \alpha = \frac{\text{adj}}{\text{hyp}} = \frac{2\sqrt{2}}{3}$$

Formula used:

equation of the line: $x \cos \alpha + y \sin \alpha = p$

$$x \times \left(\frac{2\sqrt{2}}{3}\right) + y \times \left(\frac{1}{3}\right) = 2$$

Hence $2\sqrt{2}x + y = 6$ Or $\sqrt{8}x + y = 6$ is the required equation of the line.

Question: 3

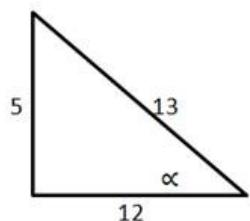

Find the equation

Solution:

To Find: The equation of the line.

$$\text{Given : } \tan \alpha = \frac{5}{12} \text{ and } p = 3 \text{ units.}$$

$$\text{Since } \tan \alpha = \frac{\text{opp}}{\text{adj}} = \frac{5}{12}$$

Using Pythagoras theorem :

$$\text{hyp} = \sqrt{25+144} = \sqrt{169} = 13 \text{ units.}$$

$$\text{From the figure: } \cos \alpha = \frac{\text{adj}}{\text{hyp}} = \frac{12}{13} \text{ and } \sin \alpha = \frac{\text{opp}}{\text{hyp}} = \frac{5}{13}$$

Formula used:

equation of the line: $x \cos \alpha + y \sin \alpha = p$

$$x \times \left(\frac{12}{13}\right) + y \times \left(\frac{5}{13}\right) = 5$$

Hence $12x + 5y = 65$ is the required equation of the line.

Exercise : 20G

Question: 1

Reduce the equati

Solution:

Given equation is $2x - 3y - 5 = 0$

We can rewrite it as $2x - 5 = 3y$

$$\Rightarrow 3y = 2x - 5$$

$$\Rightarrow y = \frac{2}{3}x - \frac{5}{3}$$

This equation is in the slope-intercept form i.e. it is the form of

$y = m \times x + c$, where m is the slope of the line and c is y-intercept of the line

Therefore, $m = \frac{2}{3}$ and $c = -\frac{5}{3}$

Conclusion: Slope is $\frac{2}{3}$ and y-intercept is $-\frac{5}{3}$

Question: 2

Reduce the equation

Solution:

Given equation is $5x + 7y - 35 = 0$

We can rewrite it as $7y = 35 - 5x$

$$\Rightarrow 7y = -5x + 35$$

$$\Rightarrow y = -\frac{5}{7}x + 5$$

This equation is in the slope-intercept form i.e. it is the form of

$y = m \times x + c$, where m is the slope of the line and c is y-intercept of the line

Therefore, $m = -\frac{5}{7}$ and $c = 5$

Conclusion: Slope is $-\frac{5}{7}$ and y-intercept is 5

Question: 3

Reduce the equation

Solution:

Given equation is $y + 5 = 0$

We can rewrite it as $y = -5$

This equation is in the slope-intercept form, i.e. it is the form of

$y = m \times x + c$, where m is the slope of the line and c is y-intercept of the line

Therefore, $m = 0$ and $c = -5$

Conclusion: Slope is 0 and y-intercept is -5

Question: 4

Reduce the equation

Solution:

Given equation is $3x - 4y + 12 = 0$

We can rewrite it as $3x - 4y = -12$

$$\Rightarrow \frac{3}{-12}x + \frac{4}{12}y = 1$$

$$\Rightarrow \frac{x}{-4} + \frac{y}{3} = 1$$

This equation is in the slope intercept form i.e. in the form $\frac{x}{a} + \frac{y}{b} = 1$

Where, x-intercept = -4 and y-intercept = 3

Two points are: (-4, 0) on the x-axis and (0, 3) on y-axis

We know distance between two points $(x_1, y_1), (x_2, y_2)$ is

$$= \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$$

$$\text{Length of the line} = \sqrt{(-4 - 0)^2 + (0 - 3)^2}$$

$$= \sqrt{16 + 9}$$

$$= \sqrt{25}$$

$$= 5$$

Conclusion: Length of the portion of the line intercepted between the axes is 5

Question: 5

Reduce the equation

Solution:

Given equation is $5x - 12y = 60$

We can rewrite it as $\frac{5}{60}x - \frac{12}{60}y = 1$

$$\Rightarrow \frac{x}{12} - \frac{y}{5} = 1$$

$$\Rightarrow \frac{x}{12} + \frac{y}{-5} = 1$$

This equation is in the slope intercept form i.e. in the form $\frac{x}{a} + \frac{y}{b} = 1$

Where, x-intercept = 12 and y-intercept = -5

Two points are: (12, 0) on the x-axis and (0, -5) on y-axis

We know the distance between two points $(x_1, y_1), (x_2, y_2)$ is

$$= \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$$

$$\text{Length of the line} = \sqrt{(12 - 0)^2 + (0 + 5)^2}$$

$$= \sqrt{144 + 25}$$

$$= \sqrt{169}$$

$$= 13$$

Conclusion: length of the portion of the line intercepted between the axes is 13

Question: 6

Find the inclination of the line.

Solution:

(i) Given equation is $x + \sqrt{3}y + 6 = 0$

We can rewrite it as $\sqrt{3}y = -x - 6$

$$\Rightarrow y = \frac{-1}{\sqrt{3}}x + \frac{-6}{\sqrt{3}}$$

It is in the form of $y = x \times \tan \alpha + c$

Where $\tan \alpha = -\frac{1}{\sqrt{3}}$ and $c = -\frac{6}{\sqrt{3}}$

The inclination of the line is α

$$\text{Therefore } \alpha = \tan^{-1}\left(\frac{-1}{\sqrt{3}}\right)$$

$$= \frac{5\pi}{6} \quad 3x + 3y = 8$$

Conclusion: Inclination of the line $x + \sqrt{3}y + 6 = 0$ is $\frac{5\pi}{6}$

$$3y = 8 - 3x$$

(ii) Given equation is

We can rewrite it as

$$\Rightarrow y = -x + \frac{-3}{8}$$

It is in the form of $y = x \times \tan \alpha + c$

Where $\tan \alpha = -1$ and $c = -\frac{3}{8}$

$$\text{Therefore } \alpha = \tan^{-1}(-1)$$

$$= \frac{3\pi}{4}$$

Conclusion: Inclination of line $3x + 3y + 8 = 0$ is $\frac{3\pi}{4}$

(iii) Given equation is $\sqrt{3}x - y - 4 = 0$

We can rewrite it as $y = \sqrt{3}x - 4$

It is in the form of $y = x \times \tan \alpha + c$

Where $\tan \alpha = \sqrt{3}$ and $c = -4$

$$\Rightarrow \alpha = \tan^{-1}(\sqrt{3})$$

$$= \frac{\pi}{3}$$

Conclusion: Inclination of the line is $\frac{\pi}{3}$

Question: 7

Reduce the equation

Solution:

Given equation is $x + y - \sqrt{2} = 0$

If the equation is in the form of $ax + by = c$, to get into the normal form, we should divide it by $\sqrt{a^2 + b^2}$, so now

Divide by $\sqrt{1+1} = \sqrt{2}$

$$\Rightarrow \frac{x}{\sqrt{2}} + \frac{y}{\sqrt{2}} = 1$$

This is in the form of $x \cos \alpha + y \sin \alpha = p$

$$\cos \alpha = \frac{1}{\sqrt{2}} \Rightarrow \alpha = \cos^{-1}\left(\frac{1}{\sqrt{2}}\right)$$

$$\Rightarrow \alpha = \frac{\pi}{4} \text{ And}$$

$$\Rightarrow p = 1$$

Conclusion: $\alpha = \frac{\pi}{4}$ and $p = 1$

Question: 8

Reduce the equation

Solution:

Given equation is $x + \sqrt{3}y - 4 = 0$

If the equation is in the form of $ax + by = c$, to get into the normal form, we should divide it by $\sqrt{a^2 + b^2}$, so now

Divide by $\sqrt{\sqrt{3}^2 + 1^2} = 2$

$$\text{Now we get } \Rightarrow \frac{x}{2} + \frac{\sqrt{3}y}{2} = 1$$

This is in the form of $x \cos \alpha + y \sin \alpha = p$

$$\text{Where } \cos \alpha = \frac{1}{2} \Rightarrow \alpha = \frac{\pi}{3}$$

$$\text{And } p = 1$$

Conclusion: $\alpha = \frac{\pi}{3}$ and $p = 1$

Question: 9

Reduce each of the

Solution:

$$\Rightarrow x + y = 2$$

If the equation is in the form of $ax + by = c$, to get into the normal form we should divide it by $\sqrt{a^2 + b^2}$, so now

$$\text{Divide by } \sqrt{1^2 + 1^2} = \sqrt{2}$$

$$\Rightarrow \frac{x}{\sqrt{2}} + \frac{y}{\sqrt{2}} = \frac{2}{\sqrt{2}}$$

$$\Rightarrow \frac{x}{\sqrt{2}} + \frac{y}{\sqrt{2}} = \sqrt{2}$$

This is in the form of $x \cos \alpha + y \sin \alpha = p$, where $\alpha = \frac{\pi}{4}$ and $p = \sqrt{2}$

Conclusion: $\frac{x}{\sqrt{2}} + \frac{y}{\sqrt{2}} = \sqrt{2}$ is the normal form of $x + y - 2 = 0$

$$(ii) x + y + \sqrt{2} = 0$$

$$\Rightarrow x + y = -\sqrt{2}$$

If the equation is in the form of $ax + by = c$, to get into the normal form, we should divide it by $\sqrt{a^2 + b^2}$, so now

$$\text{Divide by } \sqrt{1^2 + 1^2} = \sqrt{2}$$

$$\text{Our new equation is } \frac{x}{-\sqrt{2}} + \frac{y}{-\sqrt{2}} = 1$$

This is in the form of $x \cos \alpha + y \sin \alpha = p$, where $\alpha = \frac{5\pi}{4}$ and $p = 1$

Conclusion: $\frac{x}{-\sqrt{2}} + \frac{y}{-\sqrt{2}} = 1$ is the normal form of $x + y + \sqrt{2} = 0$

$$(iii) \Rightarrow -x = 5$$

If the equation is in the form of $ax + by = c$, to get into the normal form, we should divide it by $\sqrt{a^2 + b^2}$, so now

$$\text{Divide the equation by } \sqrt{1^2 + 0^2} = 1$$

$$\text{Our new equation is } -x = 5$$

This is in the form of $x \cos \alpha + y \sin \alpha = p$, where $\alpha = \pi$ and $p = 5$

Conclusion: $-x = 5$ is the normal form of $x + 5 = 0$

$$(iv) \Rightarrow 2y = 3$$

If the equation is in the form of $ax + by = c$, to get into the normal form, we should divide it by $\sqrt{a^2 + b^2}$, so now

$$\text{Divide by } \sqrt{2^2 + 0^2} = 2$$

Our new equation is $y = \frac{3}{2}$

This is in the form of $x\cos\alpha + y\sin\alpha = p$, where $\alpha = \frac{\pi}{2}$ and $p = \frac{3}{2}$

Conclusion: $y = \frac{3}{2}$ is the normal form of $2y = 3$

$$(v) \Rightarrow 4x + 3y - 9 = 0$$

If the equation is in the form of $ax + by = c$, to get into the normal form, we should divide it by $\sqrt{a^2 + b^2}$, so now

$$\text{Divide by } \sqrt{4^2 + 3^2} = 5$$

Our new equation is $\frac{4}{5}x + \frac{3}{5}y = \frac{9}{5}$

This is in the form of $x\cos\alpha + y\sin\alpha = p$, where

$$\alpha = \sin^{-1}\left(\frac{3}{5}\right) \text{ or } \alpha = \cos^{-1}\left(\frac{4}{5}\right) \text{ and } p = \frac{9}{5}$$

Conclusion: $\frac{4}{5}x + \frac{3}{5}y = \frac{9}{5}$ is the normal form of $4x + 3y - 9 = 0$

Exercise : 20H

Question: 1

Find the distance

Solution:

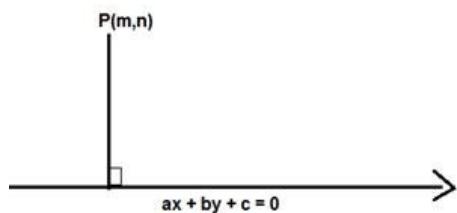

Given: Point (3,-5) and line $3x - 4y = 27$

To find: The distance of the point (3, -5) from the line $3x - 4y = 27$

Formula used:

We know that the distance between a point $P(m,n)$ and a line $ax + by + c = 0$ is given by,

$$D = \frac{|am + bn + c|}{\sqrt{a^2 + b^2}}$$

The equation of the line is $3x - 4y - 27 = 0$

Here $m = 3$ and $n = -5$, $a = 3$, $b = -4$, $c = -27$

$$D = \frac{|3(3) - 4(-5) - 27|}{\sqrt{3^2 + 4^2}}$$

$$D = \frac{|9 + 20 - 27|}{\sqrt{9 + 16}} = \frac{|29 - 27|}{\sqrt{25}} = \frac{|2|}{5}$$

$$D = \frac{2}{5}$$

The distance of the point (3, -5) from the line $3x - 4y = 27$ is $\frac{2}{5}$ units

Question: 2

Find the distance

Solution:

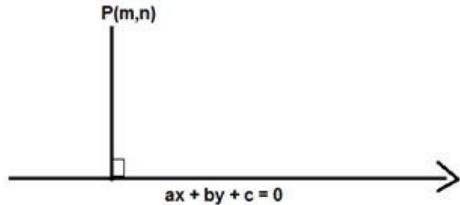

Given: Point (-2,3) and line $12x - 5y = 13$

To find: The distance of the point (-2, 3) from the line $12x - 5y = 13$

Formula used:

We know that the distance between a point P (m,n) and a line $ax + by + c = 0$ is given by,

$$D = \frac{|am+bn+c|}{\sqrt{a^2+b^2}}$$

The given equation of the line is $12x - 5y - 13 = 0$

Here $m = -2$ and $n = 3$, $a = 12$, $b = -5$, $c = -13$

$$D = \frac{|12(-2)-5(3)-13|}{\sqrt{12^2+5^2}}$$

$$D = \frac{|-24-15-13|}{\sqrt{144+25}} = \frac{|-52|}{\sqrt{169}} = \frac{|-52|}{13} = \frac{52}{13} = 4$$

$$D = 4$$

The distance of the point (-2, 3) from the line $12x - 5y - 13 = 0$ is 4 units

Question: 3

Find the distance

Solution:

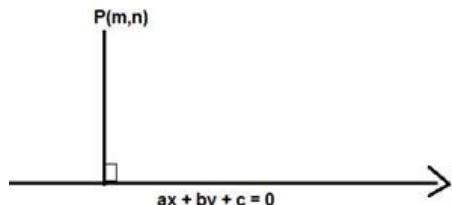

Given: Point (-4,3) and line $4(x + 5) = 3(y - 6)$

To find: The distance of the point (-4, 3) from the line $4(x + 5) = 3(y - 6)$

Formula used:

We know that the distance between a point P (m,n) and a line $ax + by + c = 0$ is given by,

$$D = \frac{|am+bn+c|}{\sqrt{a^2+b^2}}$$

The equation of the line is $4x + 20 = 3y - 18$

$$4x - 3y + 38 = 0$$

Here $m = -4$ and $n = 3$, $a = 4$, $b = -3$, $c = 38$

$$D = \frac{|4(-4)-3(3)+38|}{\sqrt{4^2+3^2}}$$

$$D = \frac{|-16-9+38|}{\sqrt{16+9}} = \frac{|-25+38|}{\sqrt{25}} = \frac{|13|}{5}$$

$$D = \frac{13}{5}$$

The distance of the point (-4, 3) from the line $4(x + 5) = 3(y - 6)$ is $\frac{13}{5}$ units

Question: 4

Find the distance

Solution:

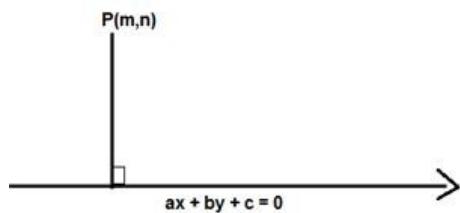

Given: Point (2,3) and line $y = 4$

To find: The distance of the point (2, 3) from the line $y = 4$

Formula used:

We know that the distance between a point P (m,n) and a line $ax + by + c = 0$ is given by,

$$D = \frac{|am+bn+c|}{\sqrt{a^2+b^2}}$$

The equation of the line is $y - 4 = 0$

Here $m = 2$ and $n = 3$, $a = 0$, $b = 1$, $c = -4$

$$D = \frac{|1(3)-4|}{\sqrt{0^2+1^2}}$$

$$D = \frac{|3-4|}{\sqrt{0+1}} = \frac{|-1|}{\sqrt{1}} = 1$$

$$D = 1$$

The distance of the point (2, 3) from the line $y = 4$ is 1 units

Question: 5

Given: Point (4,2) and the line joining the points (4, 1) and (2, 3)

To find: The distance of the point (4,2) from the line joining the points (4, 1) and (2, 3)

Formula used:

The equation of the line joining the points (x_1, y_1) and (x_2, y_2) is given by

$$\frac{y - y_1}{y_2 - y_1} = \frac{x - x_1}{x_2 - x_1}$$

Here $x_1 = 4$ $y_1 = 1$ and $x_2 = 2$ $y_2 = 3$

$$\frac{y - 1}{x - 4} = \frac{3 - 1}{2 - 4} = \frac{2}{-2} = -1$$

$$y - 1 = -x + 4$$

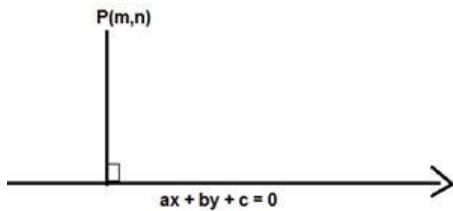

$$x + y - 5 = 0$$

The equation of the line is $x + y - 5 = 0$

Formula used:

We know that the distance between a point P (m,n) and a line $ax + by + c = 0$ is given by,

$$D = \frac{|am+bn+c|}{\sqrt{a^2+b^2}}$$

The equation of the line is $x + y - 5 = 0$

Here $m = 4$ and $n = 2$, $a = 1$, $b = 1$, $c = -5$

$$D = \frac{|1(4)+1(2)-5|}{\sqrt{1^2+1^2}}$$

$$D = \frac{|4+2-5|}{\sqrt{1+1}} = \frac{|6-5|}{\sqrt{2}} = \frac{|1|}{\sqrt{2}}$$

$$D = \frac{1}{\sqrt{2}} = \frac{\sqrt{2}}{2}$$

The distance of the point (4,2) from the line joining the points (4, 1) and (2, 3) is $\frac{\sqrt{2}}{2}$ units

Question: 6

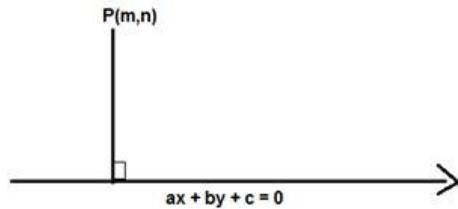

Given: Point (0,0) and line $7x + 24y = 50$

To find: The length of the perpendicular from the origin to the line $7x + 24y = 50$

Formula used:

We know that the length of the perpendicular from P (m,n) to the line $ax + by + c = 0$ is given by,

$$D = \frac{|am+bn+c|}{\sqrt{a^2+b^2}}$$

The given equation of the line is $7x + 24y - 50 = 0$

Here $m = 0$ and $n = 0$, $a = 7$, $b = 24$, $c = -50$

$$D = \frac{|7(0)+24(0)-50|}{\sqrt{7^2+24^2}}$$

$$D = \frac{|0+0-50|}{\sqrt{49+576}} = \frac{|-50|}{\sqrt{625}} = \frac{|-50|}{25} = \frac{50}{25} = 2$$

$$D = 2$$

The length of perpendicular from the origin to the line $7x + 24y = 50$ is 2 units

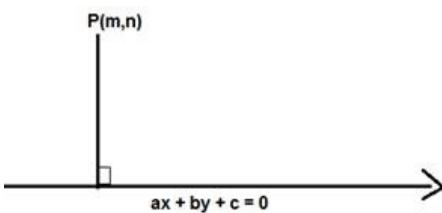

(ii) Given: Point (0,0) and line $4x + 3y = 9$

To find: The length of perpendicular from the origin to the line $4x + 3y = 9$

Formula used:

We know that the length of perpendicular from P (m,n) to the line $ax + by + c = 0$ is given by,

$$D = \frac{|am+bn+c|}{\sqrt{a^2+b^2}}$$

The given equation of the line is $4x + 3y - 9 = 0$

Here $m = 0$ and $n = 0$, $a = 4$, $b = 3$, $c = -9$

$$D = \frac{|4(0) + 3(0) - 9|}{\sqrt{4^2 + 3^2}}$$

$$D = \frac{|0+0-9|}{\sqrt{16+9}} = \frac{|-9|}{\sqrt{25}} = \frac{|-9|}{5} = \frac{9}{5}$$

$$D = \frac{9}{5}$$

The length of perpendicular from the origin to the line $4x + 3y = 9$ is $\frac{9}{5}$ units

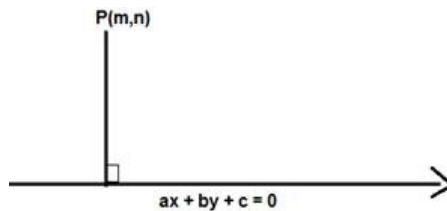

(iii) Given: Point $(0,0)$ and line $x = 4$

To find: The length of perpendicular from the origin to the line $x = 4$

Formula used:

We know that the length of perpendicular from (m,n) to the line $ax + by + c = 0$ is given by,

$$D = \frac{|am + bn + c|}{\sqrt{a^2 + b^2}}$$

The given equation of the line is $x - 4 = 0$

Here $m = 0$ and $n = 0$, $a = 1$, $b = 0$, $c = -4$

$$D = \frac{|1(0) + 0(0) - 4|}{\sqrt{1^2 + 0^2}}$$

$$D = \frac{|0+0-4|}{\sqrt{1+0}} = \frac{|-4|}{\sqrt{1}} = \frac{|-4|}{1} = 4$$

$$D = 4$$

The length of perpendicular from the origin to the line $x = 4$ is 4 units

Question: 7

Prove that the pr

Solution:

Given: Point $A(\sqrt{a^2 - b^2}, 0)$, $B(-\sqrt{a^2 - b^2}, 0)$ and line $\frac{x}{a} \cos \theta + \frac{y}{b} \sin \theta = 1$

To Prove: The product of the lengths of perpendiculars drawn from the points

$A(\sqrt{a^2 - b^2}, 0)$ and $B(-\sqrt{a^2 - b^2}, 0)$ to the line $\frac{x}{a} \cos \theta + \frac{y}{b} \sin \theta = 1$, is b^2

Formula used:

We know that the length of the perpendicular from (m,n) to the line $ax + by + c = 0$ is given by,

$$D = \frac{|am+bn+c|}{\sqrt{a^2+b^2}}$$

The equation of the line is $\frac{x}{a} \cos \theta + \frac{y}{b} \sin \theta - 1 = 0$

At point A, $m = \sqrt{a^2 - b^2}$ and $n = 0$, $a = \frac{\cos \theta}{a}$ $b = \frac{\sin \theta}{b}$ $c = -1$

$$D_1 = \frac{\left| \frac{\cos \theta}{a} (\sqrt{a^2 - b^2}) + \frac{\sin \theta}{b} (0) - 1 \right|}{\sqrt{\left(\frac{\cos \theta}{a}\right)^2 + \left(\frac{\sin \theta}{b}\right)^2}}$$

$$D_1 = \frac{\left| \frac{\cos \theta}{a} (\sqrt{a^2 - b^2}) - 1 \right|}{\sqrt{\frac{\cos^2 \theta}{a^2} + \frac{\sin^2 \theta}{b^2}}}$$

At point B, $m = -\sqrt{a^2 - b^2}$ and $n = 0$, $a = \frac{\cos \theta}{a}$ $b = \frac{\sin \theta}{b}$ $c = -1$

$$D_2 = \frac{\left| \frac{\cos \theta}{a} (-\sqrt{a^2 - b^2}) + \frac{\sin \theta}{b} (0) - 1 \right|}{\sqrt{\left(\frac{\cos \theta}{a}\right)^2 + \left(\frac{\sin \theta}{b}\right)^2}}$$

$$D_2 = \frac{\left| \frac{\cos \theta}{a} (-\sqrt{a^2 - b^2}) - 1 \right|}{\sqrt{\frac{\cos^2 \theta}{a^2} + \frac{\sin^2 \theta}{b^2}}} = \frac{\left| \frac{\cos \theta}{a} (\sqrt{a^2 - b^2}) + 1 \right|}{\sqrt{\frac{\cos^2 \theta}{a^2} + \frac{\sin^2 \theta}{b^2}}}$$

Product of the lengths of perpendiculars drawn from the points A and B is $D_1 \times D_2$

$$D_1 \times D_2 = \frac{\left| \frac{\cos \theta}{a} (\sqrt{a^2 - b^2}) - 1 \right|}{\sqrt{\frac{\cos^2 \theta}{a^2} + \frac{\sin^2 \theta}{b^2}}} \times \frac{\left| \frac{\cos \theta}{a} (\sqrt{a^2 - b^2}) + 1 \right|}{\sqrt{\frac{\cos^2 \theta}{a^2} + \frac{\sin^2 \theta}{b^2}}} = \frac{\left| \frac{\cos^2 \theta}{a^2} (a^2 - b^2) - 1 \right|}{\frac{\cos^2 \theta}{a^2} + \frac{\sin^2 \theta}{b^2}}$$

(In the numerator we have $(x - y) \times (x + y) = x^2 + y^2$ and $\sin^2 \theta + \cos^2 \theta$)

$$D_1 \times D_2 = \frac{\left| \frac{\cos^2 \theta \times a^2}{a^2} + \frac{\cos^2 \theta \times (-b^2)}{a^2} - \cos^2 \theta - \sin^2 \theta \right|}{\frac{\cos^2 \theta + \sin^2 \theta}{a^2 + b^2}} = \frac{\left| \frac{\cos^2 \theta + \cos^2 \theta \times (-b^2)}{a^2} - \cos^2 \theta - \sin^2 \theta \right|}{\frac{\cos^2 \theta + \sin^2 \theta}{a^2 + b^2}}$$

$$D_1 \times D_2 = \frac{\left| \frac{\cos^2 \theta \times (-b^2)}{a^2} - \sin^2 \theta \right|}{\frac{\cos^2 \theta + \sin^2 \theta}{a^2 + b^2}} = b^2 \times \frac{\frac{a^2}{\cos^2 \theta + \sin^2 \theta} - b^2}{\frac{a^2}{\cos^2 \theta + \sin^2 \theta}} = b^2$$

$$D_1 \times D_2 = b^2$$

Product of the lengths of perpendiculars drawn from the points A and B is b^2

Question: 8

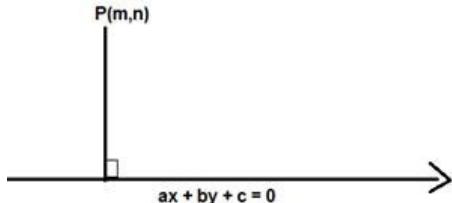

Given: Point $(4,1)$, line $3x - 4y + k = 0$ and length of perpendicular is 2 units

To find: The values of k

Formula used:

We know that the length of the perpendicular from (m,n) to the line $ax + by + c = 0$ is given by,

$$D = \frac{|am+bn+c|}{\sqrt{a^2+b^2}}$$

The equation of the line is $3x - 4y + k = 0$

Here m= 4 and n= 1 , a = 3 , b = -4 , c = k and D=2 units

$$D = \frac{|3(4)-4(1)+k|}{\sqrt{3^2+4^2}} = 2$$

$$D = \frac{|12-4+k|}{\sqrt{9+16}} = \frac{|8+k|}{\sqrt{25}} = \frac{|8+k|}{5} = 2$$

$$|8+k| = 2 \times 5 = 10$$

$$8+k = 10 \text{ or } 8+k = -10$$

$$k = 10-8 \text{ or } k = -10-8$$

$$k = 2 \text{ or } k = -18$$

The values of k are 2 and -18

Question: 9

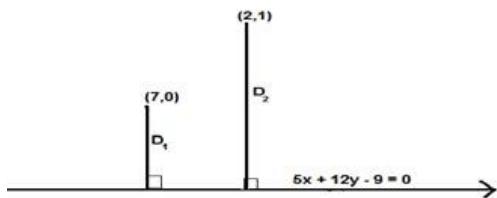

Given: Points (7,0) and (2,1) , line $5x + 12y - 9 = 0$

To Prove : length of the perpendicular from the point (7, 0) to the line $5x + 12y - 9 = 0$ is double the length of perpendicular to it from the point (2, 1)

Formula used:

We know that the length of the perpendicular from (m,n) to the line $ax + by + c = 0$ is given by,

$$D = \frac{|am + bn + c|}{\sqrt{a^2 + b^2}}$$

Let D_1 be the length of perpendicular from the point (7, 0) to the line $5x + 12y - 9 = 0$

The given equation of the line is $5x + 12y - 9 = 0$

Here at point (7,0) m= 7 and n= 0 , a = 5 , b = 12 , c = -9

$$D_1 = \frac{|5(7)+12(0)-9|}{\sqrt{5^2+12^2}}$$

$$D_1 = \frac{|35+0-9|}{\sqrt{25+144}} = \frac{26}{\sqrt{169}} = \frac{26}{13} = 2$$

$$D_1 = 2$$

Let D_2 be the length of perpendicular from the point (2, 1) to the line $5x + 12y - 9 = 0$

The given equation of the line is $5x + 12y - 9 = 0$

Here at point (2,1) m= 2 and n= 1 , a = 5 , b = 12 , c = -9

$$D_2 = \frac{|5(2)+12(1)-9|}{\sqrt{5^2+12^2}}$$

$$D_2 = \frac{|10+12-9|}{\sqrt{25+144}} = \frac{22-9}{\sqrt{169}} = \frac{13}{13} = 1$$

$$D_2 = 1$$

$$D_1=2D_2=2$$

Thus the length of the perpendicular from the point (7, 0) to the line $5x + 12y - 9 = 0$ is double the length of perpendicular to it from the point (2, 1)

Question: 10

Given: points A(2, 3), B(4, -1) and C(-1, 2) are the vertices of ΔABC

To find : length of the perpendicular from C on AB and the area of ΔABC

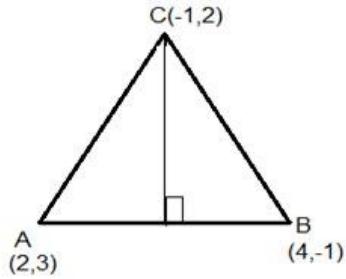

Formula used:

We know that the length of the perpendicular from (m,n) to the line $ax + by + c = 0$ is given by,

$$D = \frac{|am + bn + c|}{\sqrt{a^2 + b^2}}$$

The equation of the line joining the points (x_1, y_1) and (x_2, y_2) is given by

$$\frac{y - y_1}{y_2 - y_1} = \frac{x - x_1}{x_2 - x_1}$$

The equation of the line joining the points A(2,3) and B(4,-1) is

Here $x_1 = 2$ $y_1 = 3$ and $x_2 = 4$ $y_2 = -1$

$$\frac{y - 3}{x - 2} = \frac{-1 - 3}{4 - 2} = \frac{-4}{2} = -2$$

$$y - 3 = -2x + 4$$

$$2x + y - 7 = 0$$

The equation of the line is $2x + y - 7 = 0$

The length of perpendicular from C(-1, 2) to the line AB

The given equation of the line is $2x + y - 7 = 0$

Here $m = -1$ and $n = 2$, $a = 2$, $b = 1$, $c = -7$

$$D = \frac{|2(-1) + 1(2) - 7|}{\sqrt{2^2 + 1^2}}$$

$$D = \frac{-2 + 2 - 7}{\sqrt{4+1}} = \frac{|-7|}{\sqrt{5}} = \frac{|-7|}{\sqrt{5}} = \frac{7}{\sqrt{5}}$$

$$D = \frac{7}{\sqrt{5}}$$

The length of the perpendicular from C on AB is $\frac{7}{\sqrt{5}}$ units.

Height of the triangle is $\frac{7}{\sqrt{5}}$ units

The distance between points A(x₁, y₁) and B(x₂, y₂) is given by

$$AB = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

Here x₁=2 and y₁=3 ,x₂=4 and y₂=-1

$$AB = \sqrt{(4-2)^2 + (-1-3)^2} = \sqrt{2^2 + (-4)^2} = \sqrt{4+16} = \sqrt{20} = 2\sqrt{5}$$

Base AB = $2\sqrt{5}$ units

$$\text{Area of the triangle} = \frac{1}{2} \times \text{BASE} \times \text{HEIGHT}$$

$$\text{Area of the triangle ABC} = \frac{1}{2} \times AB \times \text{HEIGHT} = \frac{1}{2} \times 2\sqrt{5} \times \frac{7}{\sqrt{5}} = 7$$

Area of the triangle ABC = 7 square units

Question: 11

Given: perpendicular distance is 4 units and line $\frac{x}{3} + \frac{y}{4} = 1$

To find : points on the x-axis

Formula used:

We know that the length of the perpendicular from (m,n) to the line ax + by + c = 0 is given by,

$$D = \frac{|am + bn + c|}{\sqrt{a^2 + b^2}}$$

The equation of the line is $4x + 3y - 12 = 0$

Any point on the x-axis is given by (x,0)

Here m= x and n= 0 , a = 4 , b = 3 , c = -12 and D=4 units

$$D = \frac{|4(x) + 3(0) - 12|}{\sqrt{4^2 + 3^2}} = 4$$

$$D = \frac{|4x - 12|}{\sqrt{16+9}} = \frac{|4x - 12|}{\sqrt{25}} = \frac{|4x - 12|}{5} = 4$$

$$|4x - 12| = 4 \times 5 = 20$$

$$4x - 12 = 20 \text{ or } 4x - 12 = -20$$

$$4x = 20 + 12 \text{ or } 4x = -20 + 12$$

$$4x = 32 \text{ or } 4x = -8$$

$$x = 32/4 = 8 \text{ or } x = (-8)/4 = -2$$

(8,0) and (2,0)are the points on the x-axis whose perpendicular distance from the line is 4 units

Question: 12

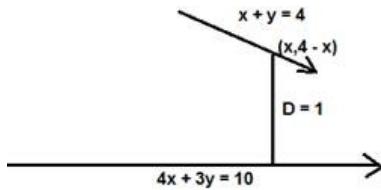

Given: points lie on the line x + y = 4 , perpendicular distance = 1 units

To find : points on the line x + y = 4

Formula used:

We know that the distance between a point (m,n) and a line $ax + by + c = 0$ is given by,

$$D = \frac{|am + bn + c|}{\sqrt{a^2 + b^2}}$$

The equation of the line is $4x + 3y - 10 = 0$ and $D=1$ units

Here $m = x$ and $n = 4 - x$ (from the equation $x + y = 4$), $a = 4$, $b = 3$, $c = -10$

$$D = \frac{|4(x) + 3(4-x) - 10|}{\sqrt{4^2 + 3^2}} = 1$$

$$D = \frac{|4x + 12 - 3x - 10|}{\sqrt{16+9}} = \frac{|x-2|}{\sqrt{25}} = \frac{|x-2|}{5} = 1$$

$$|x-2| = 1 \times 5 = 5$$

$$x-2=5 \text{ or } x-2=-5$$

$$x=5+2 \text{ or } x=-5+2$$

$$x=7 \text{ or } x=-3$$

We know that the points lie on the line $x + y = 4$

$$y = 4 - 7 = -3 \text{ or } y = 4 - (-3) = 7$$

$(7, -3)$ and $(-3, 7)$ are the points on the line $x + y = 4$ that lie at a unit distance from

$$4x + 3y = 10.$$

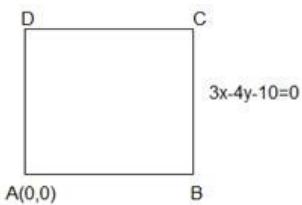

Question: 13

A vertex of a square

Solution:

Given: ABCD is a square and equation of BC is $3x - 4y - 10 = 0$

To find : Area of the square

Formula used:

We know that the length of perpendicular from (m,n) to the line $ax + by + c = 0$ is given by,

$$D = \frac{|am + bn + c|}{\sqrt{a^2 + b^2}}$$

The given equation of the line is $3x - 4y - 10 = 0$

Here $m = 0$ and $n = 0$, $a = 3$, $b = -4$, $c = -10$

$$D = \frac{|3(0) - 4(0) - 10|}{\sqrt{3^2 + 4^2}}$$

$$D = \frac{|0 + 0 - 10|}{\sqrt{9+16}} = \frac{|-10|}{\sqrt{25}} = \frac{|-10|}{5} = \frac{10}{5} = 2$$

$$D = 2$$

Side of the square = D = 2

Area of the square = $2 \times 2 = 4$ square units

Area of the square = 4 square units

Question: 14

Find the distance

Solution:

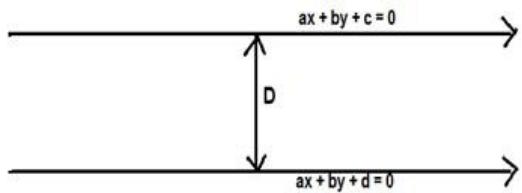

Given: parallel lines $4x - 3y + 5 = 0$ and $4x - 3y + 7 = 0$

To find : distance between the parallel lines

Formula used :

The distance between the parallel lines $ax + by + c = 0$ and $ax + by + d = 0$ is,

$$D = \frac{|d - c|}{\sqrt{a^2 + b^2}}$$

Here $a = 4, b = -3, c = 5, d = 7$

$$D = \frac{|7 - 5|}{\sqrt{4^2 + (-3)^2}} = \frac{|2|}{\sqrt{16+9}} = \frac{2}{\sqrt{25}} = \frac{2}{5}$$

The distance between the parallel lines $4x - 3y + 5 = 0$ and $4x - 3y + 7 = 0$ is $\frac{2}{5}$ units

Question: 15

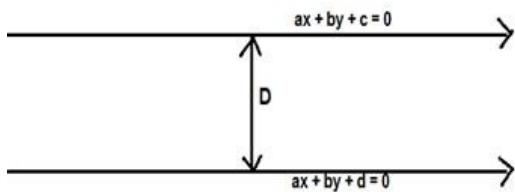

Given: parallel lines $8x + 15y - 36 = 0$ and $8x + 15y + 32 = 0$.

To find : distance between the parallel lines

Formula used :

The distance between the parallel lines $ax + by + c = 0$ and $ax + by + d = 0$ is,

$$D = \frac{|d - c|}{\sqrt{a^2 + b^2}}$$

Here $a = 8, b = 15, c = -36, d = 32$

$$D = \frac{|32 - (-36)|}{\sqrt{8^2 + 15^2}} = \frac{|32 + 36|}{\sqrt{64 + 225}} = \frac{68}{\sqrt{289}} = \frac{68}{17} = 4$$

The distance between the parallel lines $8x + 15y - 36 = 0$ and $8x + 15y + 32 = 0$ is 4 Units

Question: 16

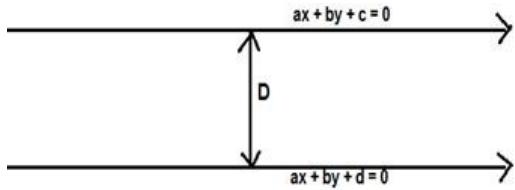

Given: parallel lines $y = mx + c$ and $y = mx + d$

To find : distance between the parallel lines

Formula used :

The distance between the parallel lines $ax + by + c = 0$ and $ax + by + d = 0$ is,

$$D = \frac{|d - c|}{\sqrt{a^2 + b^2}}$$

The parallel lines are $mx - y + c = 0$ and $mx - y + d = 0$

Here $a = m, b = -1, c = c, d = d$

$$D = \frac{|d - c|}{\sqrt{m^2 + 1^2}} = \frac{|d - c|}{\sqrt{m^2 + 1}}$$

The distance between the parallel lines $y = mx + c$ and $y = mx + d$ is $\frac{|d - c|}{\sqrt{m^2 + 1}}$ units

Question: 17

Find the distance

Solution:

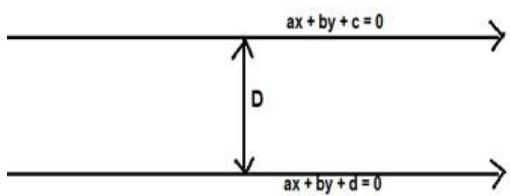

Given: parallel lines $p(x + y) = q = 0$ and $p(x + y) - r = 0$

To find : distance between the parallel lines $p(x + y) - q = 0$ and $p(x + y) - r = 0$

Formula used :

The distance between the parallel lines $ax + by + c = 0$ and $ax + by + d = 0$ is,

$$D = \frac{|d - c|}{\sqrt{a^2 + b^2}}$$

The parallel lines are $p(x + y) - q = 0$ and $p(x + y) - r = 0$

The parallel lines are $px + py - q = 0$ and $px + py - r = 0$

Here $a = p, b = p, c = -q, d = -r$

$$D = \frac{|-r - (-q)|}{\sqrt{p^2 + p^2}} = \frac{|-r + q|}{\sqrt{2p^2}} = \frac{|q - r|}{p\sqrt{2}}$$

The distance between the parallel lines $p(x + y) = q = 0$ and $p(x + y) - r = 0$ is $\frac{|q - r|}{p\sqrt{2}}$ units

Question: 18

Prove that the li

Solution:

Given: parallel lines $12x - 5y - 3 = 0, 12x - 5y + 7 = 0, 12x - 5y - 13 = 0$

To Prove : line $12x - 5y - 3 = 0$ is mid-parallel to the lines $12x - 5y + 7 = 0$ and $12x - 5y - 13 = 0$

Formula used :

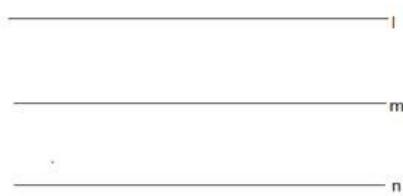

The distance between the parallel lines $ax + by + c = 0$ and $ax + by + d = 0$ is,

$$D = \frac{|d - c|}{\sqrt{a^2 + b^2}}$$

The equation of line l is $12x - 5y + 7 = 0$

The equation of line m is $12x - 5y - 3 = 0$

The equation of line n is $12x - 5y - 13 = 0$

Let D_1 be the distance between the lines l and m .

Here $a = 12, b = -5, c = 7, d = -3$

$$D_1 = \frac{|-3 - 7|}{\sqrt{12^2 + (-5)^2}} = \frac{|-10|}{\sqrt{144 + 25}} = \frac{10}{\sqrt{169}} = \frac{10}{13}.$$

The distance between the parallel lines l and m is $\frac{10}{13}$ units

Let D_2 be the distance between the lines m and n .

Here $a = 12, b = -5, c = 7, d = -3$

$$D_2 = \frac{|-13 - (-3)|}{\sqrt{12^2 + (-5)^2}} = \frac{|-13 + 3|}{\sqrt{144 + 25}} = \frac{|-10|}{\sqrt{169}} = \frac{10}{13}$$

The distance between the parallel lines m and n is $\frac{10}{13}$ units

Distance between the parallel lines l and m = Distance between the parallel lines m and n

Thus the line $12x - 5y - 3 = 0$ is mid-parallel to the lines $12x - 5y + 7 = 0$ and $12x - 5y - 13 = 0$

Question: 19

The perpendicular

Solution:

Given: perpendicular distance from origin is 5 units, and the slope is -1

To find : the equation of the line

Formula used :

We know that the perpendicular distance from a point (x_0, y_0) to the line $ax + by + c = 0$ is given by

$$D = \frac{|ax_0 + by_0 + c|}{\sqrt{a^2 + b^2}}$$

The equation of a straight line is given by $y = mx + c$ where m denotes the slope of the line.

The equation of the line is $mx - y + c = 0$

Here $x_0 = 0$ and $y_0 = 0$, $a = m$, $b = -1$, $c = c$ and $D = 5$ units

$$D = \frac{|m(0) - 1(0) + c|}{\sqrt{m^2 + 1^2}} = \frac{|c|}{\sqrt{m^2 + 1}} = \frac{|c|}{\sqrt{m^2 + 1}} = 5$$

Slope of the line = $m = -1$, Substituting in the above equation we get,

$$\frac{|c|}{\sqrt{(-1)^2 + 1^2}} = 5$$

$$\frac{|c|}{\sqrt{1+1}} = \frac{|c|}{\sqrt{2}} = 5$$

$$c = 5\sqrt{2}$$

Thus the equation of the straight line is $y = -x + 5\sqrt{2}$ or $x + y - 5\sqrt{2} = 0$

Exercise : 20I

Question: 1

Find the points o

Solution:

Suppose the given two lines intersect at a point $P(x_1, y_1)$. Then, (x_1, y_1) satisfies each of the given equations.

$$\therefore 4x + 3y = 5$$

$$\text{or } 4x + 3y - 5 = 0 \dots(i)$$

$$\text{and } x = 2y - 7$$

$$\text{or } x - 2y + 7 = 0 \dots(ii)$$

Now, we find the point of intersection of eq. (i) and (ii)

Multiply the eq. (ii) by 4, we get

$$4x - 8y + 28 = 0 \dots(iii)$$

On subtracting eq. (iii) from (i), we get

$$4x - 8y + 28 - 4x - 3y + 5 = 0$$

$$\Rightarrow -11y + 33 = 0$$

$$\Rightarrow -11y = -33$$

$$\Rightarrow y = \frac{33}{11} = 3$$

Putting the value of y in eq. (i), we get

$$4x + 3(3) - 5 = 0$$

$$\Rightarrow 4x + 9 - 5 = 0$$

$$\Rightarrow 4x + 4 = 0$$

$$\Rightarrow 4x = -4$$

$$\Rightarrow x = -1$$

Hence, the point of intersection P(x₁, y₁) is (-1, 3)

Question: 2

Show that the lin

Solution:

Suppose the given two lines intersect at a point P(2, 3). Then, (2, 3) satisfies each of the given equations.

So, taking equation x + 7y = 23

Substituting x = 2 and y = 3

$$\text{Lhs} = x + 7y$$

$$= 2 + 7(3)$$

$$= 2 + 21$$

$$= 23$$

$$= \text{RHS}$$

Now, taking equation 5x + 2y = 16

Substituting x = 2 and y = 3

$$\text{LHS} = 5x + 2y$$

$$= 5(2) + 2(3)$$

$$= 10 + 6$$

$$= 16$$

$$= \text{RHS}$$

In both the equations pair (2, 3) for (x, y) satisfies the given equations, therefore both lines pass through (2, 3).

Question: 3

Show that the lin

Solution:

Given: 3x - 4y + 5 = 0,

$$7x - 8y + 5 = 0$$

$$\text{and } 4x + 5y = 45$$

$$\text{or } 4x + 5y - 45 = 0$$

To show: Given lines are concurrent

The lines $a_1x + b_1y + c_1 = 0$, $a_2x + b_2y + c_2 = 0$ and $a_3x + b_3y + c_3 = 0$ are concurrent if

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = 0$$

We know that,

We have,

$$a_1 = 3, b_1 = -4, c_1 = 5$$

$$a_2 = 7, b_2 = -8, c_2 = 5$$

$$a_3 = 4, b_3 = 5, c_3 = -45$$

$$\Rightarrow \begin{vmatrix} 3 & -4 & 5 \\ 7 & -8 & 5 \\ 4 & 5 & -45 \end{vmatrix}$$

Now, expanding along first row, we get

$$\Rightarrow 3[(-8)(-45) - (5)(5)] - (-4)[(7)(-45) - (4)(5)] + 5[(7)(5) - (4)(-8)]$$

$$\Rightarrow 3[360 - 25] + 4[-315 - 20] + 5[35 + 32]$$

$$\Rightarrow 3[335] + 4[-335] + 5[67]$$

$$\Rightarrow 1005 - 1340 + 335$$

$$\Rightarrow 1340 - 1340$$

$$= 0$$

So, the given lines are concurrent.

Now, we have to find the point of intersection of the given lines

$$3x - 4y + 5 = 0,$$

$$7x - 8y + 5 = 0$$

$$\text{and } 4x + 5y - 45 = 0 \dots (\text{A})$$

We know that, if three lines are concurrent the point of intersection of two lines lies on the third line.

So, firstly, we find the point of intersection of two lines

$$3x - 4y + 5 = 0, \dots (\text{i})$$

$$7x - 8y + 5 = 0 \dots (\text{ii})$$

Multiply the eq. (i) by 2, we get

$$6x - 8y + 10 = 0 \dots (\text{iii})$$

On subtracting eq. (iii) from (ii), we get

$$7x - 8y + 5 - 6x + 8y - 10 = 0$$

$$\Rightarrow x - 5 = 0$$

$$\Rightarrow x = 5$$

Putting the value of x in eq. (i), we get

$$3(5) - 4y + 5 = 0$$

$$\Rightarrow 15 - 4y + 5 = 0$$

$$\Rightarrow 20 - 4y = 0$$

$$\Rightarrow -4y = -20$$

$$\Rightarrow y = 5$$

Thus, the first two lines intersect at the point (5, 5). Putting $x = 5$ and $y = 5$ in eq. (A), we get

$$4(5) + 5(5) - 45$$

$$= 20 + 25 - 45$$

$$= 45 - 45$$

$$= 0$$

So, point (5, 5) lies on line $4x + 5y - 45 = 0$

Hence, the point of intersection is (5, 5)

Question: 4

Find the value of

Solution:

Given that $3x - y - 2 = 0$,

$$5x + ky - 3 = 0$$

and $2x + y - 3 = 0$ are concurrent

We know that,

The lines $a_1x + b_1y + c_1 = 0$, $a_2x + b_2y + c_2 = 0$ and $a_3x + b_3y + c_3 = 0$ are concurrent if

$$\begin{vmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ a_3 & b_3 & c_3 \end{vmatrix} = 0$$

It is given that the given lines are concurrent.

$$\Rightarrow \begin{vmatrix} 3 & -1 & -2 \\ 5 & k & -3 \\ 2 & 1 & -3 \end{vmatrix} = 0$$

Now, expanding along first row, we get

$$\Rightarrow 3[(k)(-3) - (-3)(1)] - (-1)[(5)(-3) - (-3)(2)] + (-2)[5 - 2k] = 0$$

$$\Rightarrow 3[-3k + 3] + 1[-15 + 6] - 2[5 - 2k] = 0$$

$$\Rightarrow -9k + 9 - 9 - 10 + 4k = 0$$

$$\Rightarrow -5k - 10 = 0$$

$$\Rightarrow -5k = 10$$

$$\Rightarrow k = -2$$

Hence, the value of $k = -2$

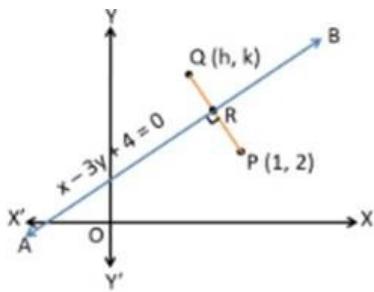

Question: 5

Find the image of

Solution:

Let line AB be $x - 3y + 4 = 0$ and point P be (1, 2)

Let the image of the point P(1, 2) in the line mirror AB be Q(h, k).

Since line AB is a mirror. Then PQ is perpendicularly bisected at R.

Since R is the midpoint of PQ.

We know that,

$$\text{Midpoint of a line joining } (x_1, y_1) \text{ & } (x_2, y_2) = \frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2}$$

$$\text{So, Midpoint of the line joining } (1, 2) \text{ & } (h, k) = \frac{1+h}{2}, \frac{2+k}{2}$$

Since point R lies on the line AB. So, it will satisfy the equation of line AB $x - 3y + 4 = 0$

Substituting the $x = \frac{1+h}{2}$ & $y = \frac{2+k}{2}$ in the equation, we get

$$\frac{1+h}{2} - 3\left(\frac{2+k}{2}\right) + 4 = 0$$

$$\Rightarrow \frac{1+h-6-3k+8}{2} = 0$$

$$\Rightarrow 3 + h - 3k = 0$$

$$\Rightarrow h - 3k = -3 \dots (\text{i})$$

Also, PQ is perpendicular to AB

We know that, if two lines are perpendicular then the product of their slope is equal to -1

$$\therefore \text{Slope of AB} \times \text{Slope of PQ} = -1$$

$$\Rightarrow \text{Slope of PQ} = \frac{-1}{\text{Slope of AB}}$$

Now, we find the slope of line AB i.e. $x - 3y + 4 = 0$

We know that, the slope of an equation is

$$m = -\frac{a}{b}$$

and here, $a = 1$ & $b = -3$

$$\Rightarrow m = -\frac{1}{(-3)} = \frac{1}{3}$$

$$= \frac{-1}{\frac{1}{3}} \\ = -3$$

Now, Equation of line PQ formed by joining the points P(1, 2) and Q(h, k) and having the slope - 3

is

$$y_2 - y_1 = m(x_2 - x_1)$$

$$\Rightarrow k - 2 = (-3)(h - 1)$$

$$\Rightarrow k - 2 = -3h + 3$$

$$\Rightarrow 3h + k = 5 \dots(\text{ii})$$

Now, we will solve the eq. (i) and (ii) to find the value of h and k

$$h - 3k = -3 \dots(\text{i})$$

$$\text{and } 3h + k = 5 \dots(\text{ii})$$

From eq. (i), we get

$$h = -3 + 3k$$

Putting the value of h in eq. (ii), we get

$$3(-3 + 3k) + k = 5$$

$$\Rightarrow -9 + 9k + k = 5$$

$$\Rightarrow -9 + 10k = 5$$

$$\Rightarrow 10k = 5 + 9$$

$$\Rightarrow 10k = 14$$

$$\Rightarrow k = \frac{14}{10} = \frac{7}{5}$$

Putting the value of k in eq. (i), we get

$$h - 3\left(\frac{7}{5}\right) = -3$$

$$\Rightarrow 5h - 21 = -3 \times 5$$

$$\Rightarrow 5h - 21 = -15$$

$$\Rightarrow 5h = -15 + 21$$

$$\Rightarrow 5h = 6$$

$$\Rightarrow h = \frac{6}{5}$$

Question: 6

Find the area of

Solution:

The given equations are

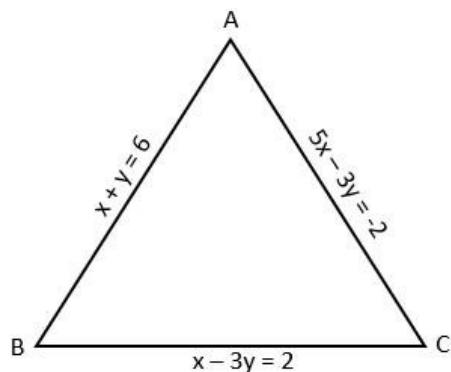

$$x + y = 6 \dots(\text{i})$$

$$x - 3y = 2 \dots(\text{ii})$$

$$\text{and } 5x - 3y + 2 = 0$$

$$\text{or } 5x - 3y = -2 \dots(\text{iii})$$

Let eq. (i), (ii) and (iii) represents the sides AB, BC and AC respectively of ΔABC

Firstly, we solve the equation (i) and (ii)

$$x + y = 6 \dots(i)$$

$$x - 3y = 2 \dots(ii)$$

Subtracting eq. (ii) from (i), we get

$$x + y - x + 3y = 6 - 2$$

$$\Rightarrow 4y = 4$$

$$\Rightarrow y = 1$$

Putting the value of $y = 1$ in eq. (i), we get

$$x + 1 = 6$$

$$\Rightarrow x = 5$$

Thus, AB and BC intersect at (5, 1)

Now, we solve eq. (ii) and (iii)

$$x - 3y = 2 \dots(ii)$$

$$5x - 3y = -2 \dots(iii)$$

Subtracting eq. (ii) from (iii), we get

$$5x - 3y - x + 3y = -2 - 2$$

$$\Rightarrow 4x = -4$$

$$\Rightarrow x = -1$$

Putting the value of $x = -1$ in eq. (ii), we get

$$-1 - 3y = 2$$

$$\Rightarrow -3y = 2 + 1$$

$$\Rightarrow -3y = 3$$

$$\Rightarrow y = -1$$

Thus, BC and AC intersect at (-1, -1)

Now, we solve eq. (iii) and (i)

$$5x - 3y = -2 \dots(iii)$$

$$x + y = 6 \dots(i)$$

From eq. (i), we get

$$x = 6 - y$$

Putting the value of x in eq. (iii), we get

$$5(6 - y) - 3y = -2$$

$$\Rightarrow 30 - 5y - 3y = -2$$

$$\Rightarrow 30 - 8y = -2$$

$$\Rightarrow -8y = -32$$

$$\Rightarrow y = 4$$

Putting the value of $y = 4$ in eq. (i), we get

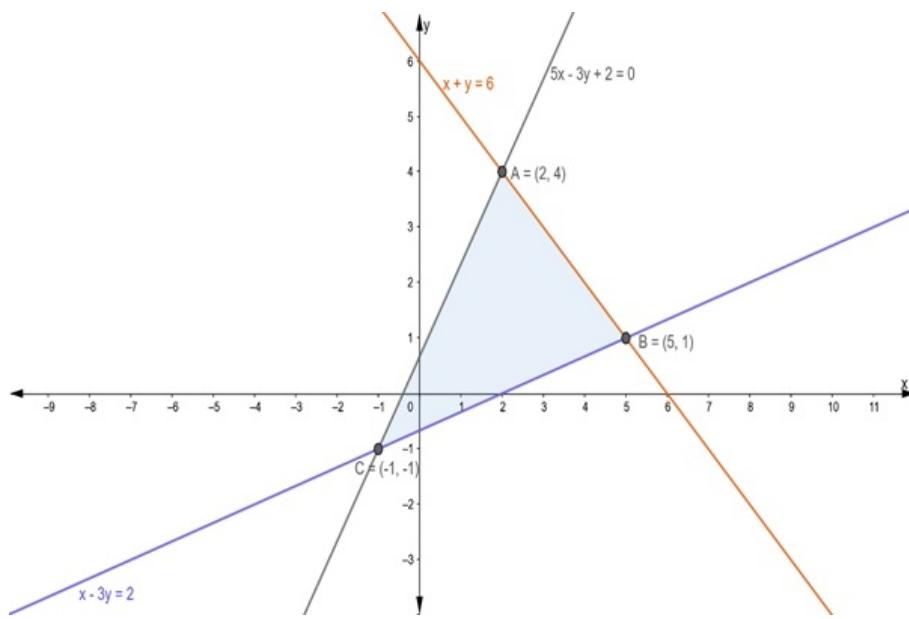

$$x + 4 = 6$$

$$\Rightarrow x = 6 - 4$$

$$\Rightarrow x = 2$$

Thus, AC and AB intersect at $(2, 4)$

So, vertices of triangle ABC are: $(5, 1)$, $(-1, -1)$ and $(2, 4)$

$$\therefore \text{Area of } \triangle ABC = \frac{1}{2} \begin{vmatrix} 2 & 4 & 1 \\ 5 & 1 & 1 \\ -1 & -1 & 1 \end{vmatrix}$$

$$= \frac{1}{2} [2\{(1)(1) - (1)(-1)\} - 4\{(5)(1) - (1)(-1)\} + 1\{(5)(-1) - (1)(-1)\}]$$

$$= \frac{1}{2} [2\{1+1\} - 4\{5+1\} + 1\{-5+1\}]$$

$$= \frac{1}{2} [4 - 24 - 4]$$

$$= \frac{1}{2} [-24]$$

$$= 12 \text{ sq. units} [\because \text{area can't be negative}]$$

Question: 7

Find the area of

Solution:

The given equations are

$$x = 0 \dots \text{(i)}$$

$$y = 1 \dots \text{(ii)}$$

$$\text{and } 2x + y = 2 \dots \text{(iii)}$$

Let eq. (i), (ii) and (iii) represents the sides AB, BC and AC respectively of ΔABC

From eq. (i) and (ii), we get $x = 0$ and $y = 1$

Thus, AB and BC intersect at $(0, 1)$

Solving eq. (ii) and (iii), we get

$$y = 1 \dots \text{(ii)}$$

$$\text{and } 2x + y = 2 \dots \text{(iii)}$$

Putting the value of $y = 1$ in eq. (iii), we get

$$2x + 1 = 2$$

$$\Rightarrow 2x = 1$$

$$\Rightarrow x = \frac{1}{2}$$

Thus, BC and AC intersect at $\left(\frac{1}{2}, 1\right)$

Now, Solving eq. (iii) and (i), we get

$$2x + y = 2 \dots \text{(iii)}$$

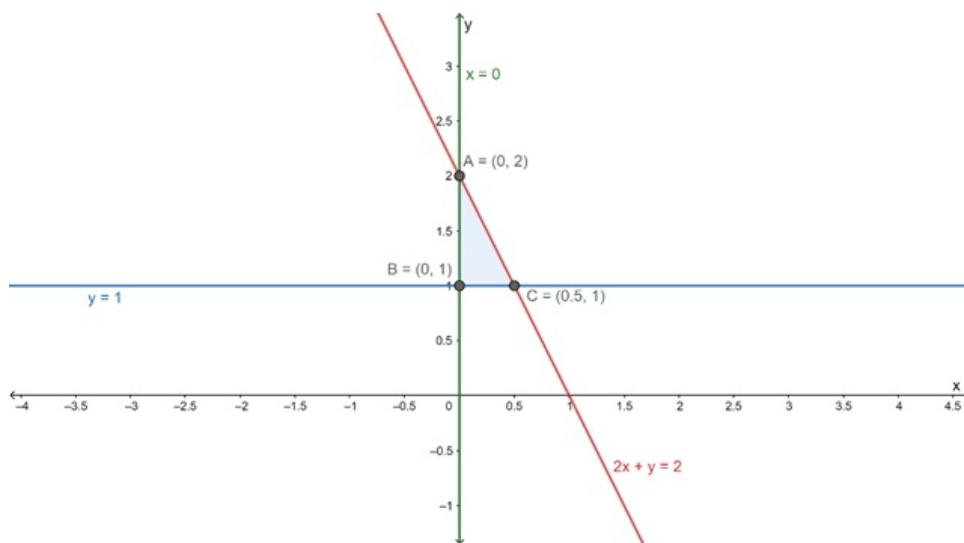

$$\text{and } x = 0 \dots \text{(i)}$$

Putting the value of $x = 0$ in eq. (iii), we get

$$y = 2$$

Thus, AC and AB intersect at $(0, 2)$

So, vertices of triangle ABC are : $(0, 1)$, $\left(\frac{1}{2}, 1\right)$ and $(0, 2)$

$$\therefore \text{Area of } \Delta ABC = \frac{1}{2} \times \text{base} \times \text{height}$$

$$= \frac{1}{2} \times \frac{1}{2} \times 1$$

$$= \frac{1}{4} \text{ sq. units}$$

Question: 8

Find the area of

Solution:

The given equations are

$$y = x \dots (\text{i})$$

$$y = 2x \dots (\text{ii})$$

$$\text{and } y - 3x = 4 \dots (\text{iii})$$

Let eq. (i), (ii) and (iii) represents the sides AB, BC and AC respectively of ΔABC

From eq. (i) and (ii), we get $x = 0$ and $y = 0$

Thus, AB and BC intersect at $(0, 0)$

Solving eq. (ii) and (iii), we get

$$y = 2x \dots (\text{ii})$$

$$\text{and } y - 3x = 4 \dots (\text{iii})$$

Putting the value of $y = 2x$ in eq. (iii), we get

$$2x - 3x = 4$$

$$\Rightarrow -x = 4$$

$$\Rightarrow x = -4$$

Putting the value of $x = -4$ in eq. (ii), we get

$$y = 2(-4)$$

$$\Rightarrow y = -8$$

Thus, BC and AC intersect at $(-4, -8)$

Now, Solving eq. (iii) and (i), we get

$$y - 3x = 4 \dots (\text{iii})$$

$$\text{and } y = x \dots (\text{i})$$

Putting the value of $y = x$ in eq. (iii), we get

$$x - 3x = 4$$

$$\Rightarrow -2x = 4$$

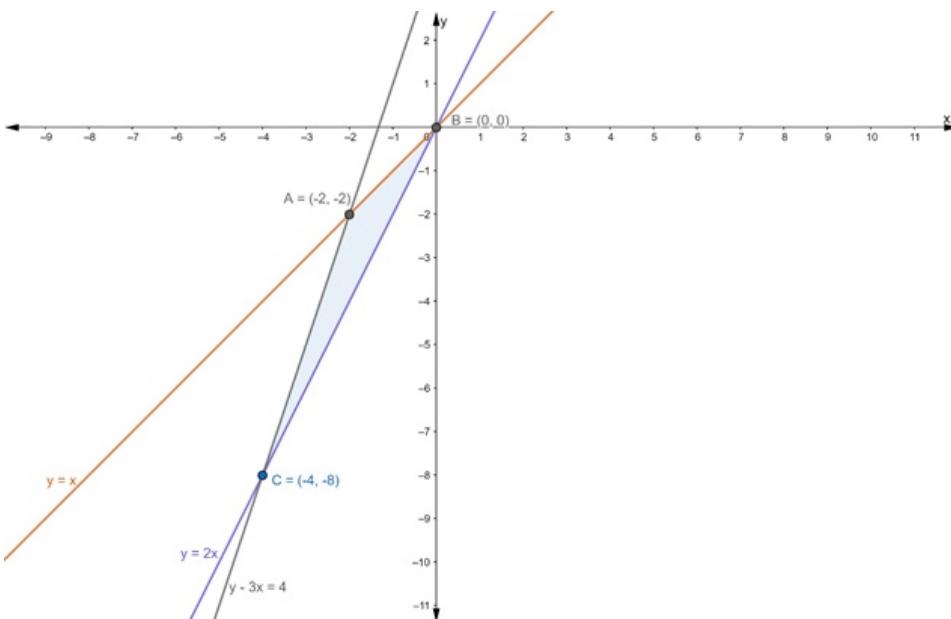

$$\Rightarrow x = -2$$

Putting the value of $x = -2$ in eq. (i), we get

$$y = -2$$

Thus, AC and AB intersect at $(-2, -2)$

So, vertices of triangle ABC are: $(0, 0)$, $(-4, -8)$ and $(-2, -2)$

$$\therefore \text{Area of } \triangle ABC = \frac{1}{2} \begin{vmatrix} 0 & 0 & 1 \\ -2 & -2 & 1 \\ -4 & -8 & 1 \end{vmatrix}$$

$$= \frac{1}{2} [0 - 0 + 1 \{(-2)(-8) - (-2)(-4)\}]$$

$$= \frac{1}{2} [1 \{16 - 8\}]$$

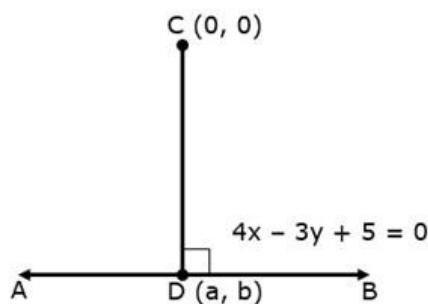

$$= \frac{1}{2} [8]$$

$$= 4 \text{ sq. units}$$

Question: 9

Find the equation

Solution:

Let the equation of line AB be $4x - 3y + 5 = 0$

and point C be $(0, 0)$

CD is perpendicular to the line AB, and we need to find:

1) Equation of Perpendicular drawn from point C

2) Coordinates of D

Let the coordinates of point D be (a, b)

Also, point D(a, b) lies on the line AB, i.e. point (a, b) satisfy the equation of line AB

Putting $x = a$ and $y = b$, in equation, we get

$$4a - 3b + 5 = 0 \dots(i)$$

Also, the CD is perpendicular to the line AB

and we know that, if two lines are perpendicular then the product of their slope is equal to -1

$$\therefore \text{Slope of } AB \times \text{Slope of } CD = -1$$

$$\Rightarrow \text{Slope of } CD = \frac{-1}{\text{Slope of } AB}$$

$$= \frac{-1}{\frac{4}{3}}$$

$$\text{Slope of } CD = -\frac{3}{4}$$

Now, Equation of line CD formed by joining the points C(0, 0) and D(a, b) and having the slope

$$-\frac{3}{4} \text{ is}$$

$$y_2 - y_1 = m(x_2 - x_1)$$

$$\Rightarrow b - 0 = -\frac{3}{4}(a - 0)$$

$$\Rightarrow b = -\frac{3}{4}a$$

$$\Rightarrow 4b = -3a$$

$$\Rightarrow 3a + 4b = 0 \dots(ii)$$

Now, our equations are

$$4a - 3b + 5 = 0 \dots(i)$$

$$\text{and } 3a + 4b = 0 \dots(ii)$$

Multiply the eq. (i) by 4 and (ii) by 3, we get

$$16a - 12b + 20 = 0 \dots(iii)$$

$$9a + 12b = 0 \dots(iv)$$

Adding eq. (iii) and (iv), we get

$$16a - 12b + 20 + 9a + 12b = 0$$

$$\Rightarrow 25a + 20 = 0$$

$$\Rightarrow 25a = -20$$

$$\Rightarrow a = -\frac{20}{25} = -\frac{4}{5}$$

Putting the value of a in eq. (ii), we get

$$3\left(-\frac{4}{5}\right) + 4b = 0$$

$$\Rightarrow -\frac{12}{5} + 4b = 0$$

$$\Rightarrow -12 + 20b = 0$$

$$\Rightarrow 20b = 12$$

$$\Rightarrow b = \frac{12}{20}$$

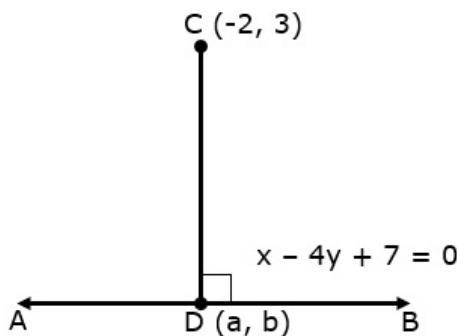

$$\Rightarrow b = \frac{3}{5}$$

Hence, the coordinates of D(a, b) is $\left(-\frac{4}{5}, \frac{3}{5}\right)$

Question: 10

Find the equation

Solution:

Let the equation of line AB be $x - 4y + 7 = 0$

and point C be (-2, 3)

CD is perpendicular to the line AB, and we need to find:

1) Equation of Perpendicular drawn from point C

2) Coordinates of D

Let the coordinates of point D be (a, b)

Also, point D(a, b) lies on the line AB, i.e. point (a, b) satisfy the equation of line AB

Putting $x = a$ and $y = b$, in equation, we get

$$a - 4b + 7 = 0 \dots(i)$$

Also, the CD is perpendicular to the line AB

and we know that, if two lines are perpendicular then the product of their slope is equal to -1

$$\therefore \text{Slope of AB} \times \text{Slope of CD} = -1$$

$$\Rightarrow \text{Slope of CD} = \frac{-1}{\text{Slope of AB}}$$

$$= \frac{-1}{\frac{1}{4}}$$

$$\text{Slope of CD} = -4$$

Now, Equation of line CD formed by joining the points C(-2, 3) and D(a, b) and having the slope -4 is

$$y_2 - y_1 = m(x_2 - x_1)$$

$$\Rightarrow b - 3 = (-4)[a - (-2)]$$

$$\Rightarrow b - 3 = -4(a + 2)$$

$$\Rightarrow b - 3 = -4a - 8$$

$$\Rightarrow 4a + b + 5 = 0 \dots(ii)$$

Now, our equations are

$$a - 4b + 7 = 0 \dots(i)$$

$$\text{and } 4a + b + 5 = 0 \dots(ii)$$

Multiply the eq. (ii) by 4, we get

$$16a + 4b + 20 = 0 \dots(iii)$$

Adding eq. (i) and (iii), we get

$$a - 4b + 7 + 16a + 4b + 20 = 0$$

$$\Rightarrow 17a + 27 = 0$$

$$\Rightarrow 17a = -27$$

$$\Rightarrow a = -\frac{27}{17}$$

Putting the value of a in eq. (i), we get

$$-\frac{27}{17} - 4b + 7 = 0$$

$$\Rightarrow \frac{-27 - 68b + 119}{17} = 0$$

$$\Rightarrow 92 - 68b = 0$$

$$\Rightarrow -68b = -92$$

$$\Rightarrow b = \frac{92}{68}$$

$$\Rightarrow b = \frac{23}{17}$$

Hence, the coordinates of D(a, b) is $\left(-\frac{27}{17}, \frac{23}{17}\right)$

Question: 11

Find the equation

Solution:

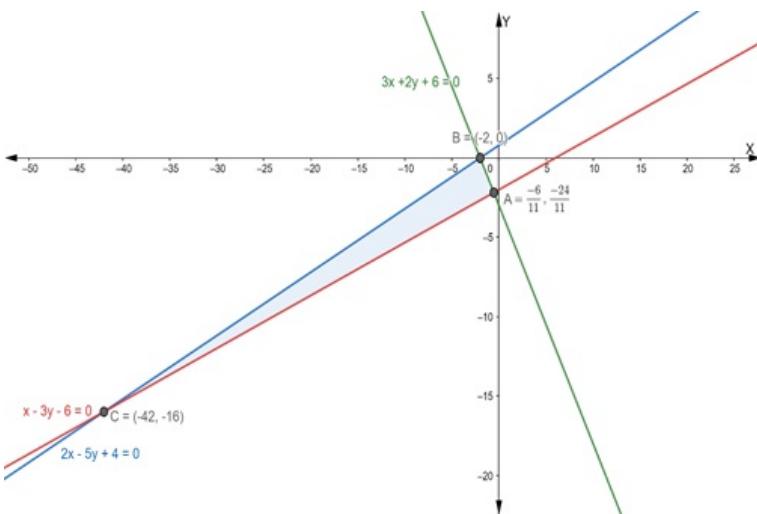

The given equations are

$$3x + 2y + 6 = 0 \dots(i)$$

$$2x - 5y + 4 = 0 \dots(ii)$$

$$\text{and } x - 3y - 6 = 0 \dots(iii)$$

Let eq. (i), (ii) and (iii) represents the sides AB, BC and AC respectively of ΔABC

Firstly, we solve the equation (i) and (ii)

$$3x + 2y + 6 = 0 \dots(i)$$

$$2x - 5y + 4 = 0 \dots(ii)$$

Multiplying the eq. (i) by 2 and (ii) by 3, we get

$$6x + 4y + 12 = 0 \dots A$$

$$6x - 15y + 12 = 0 \dots B$$

Subtracting eq. (B) from (A), we get

$$6x + 4y + 12 - 6x + 15y - 12 = 0$$

$$\Rightarrow 19y = 0$$

$$\Rightarrow y = 0$$

Putting the value of $y = 0$ in eq. (i), we get

$$3x + 2(0) + 6 = 0$$

$$\Rightarrow 3x + 6 = 0$$

$$\Rightarrow 3x = -6$$

$$\Rightarrow x = -2$$

Thus, AB and BC intersect at (-2, 0)

Now, we solve eq. (ii) and (iii)

$$2x - 5y + 4 = 0 \dots(ii)$$

$$\text{and } x - 3y - 6 = 0 \dots(iii)$$

Multiplying the eq. (iii) by 2, we get

$$2x - 6y - 12 = 0 \dots(iv)$$

Subtracting eq. (iv) from (ii), we get

$$2x - 5y + 4 - 2x + 6y + 12 = 0$$

$$\Rightarrow y + 16 = 0$$

$$\Rightarrow y = -16$$

Putting the value of $y = -16$ in eq. (ii), we get

$$2x - 5(-16) + 4 = 0$$

$$\Rightarrow 2x + 80 + 4 = 0$$

$$\Rightarrow 2x + 84 = 0$$

$$\Rightarrow 2x = -84$$

$$\Rightarrow x = -42$$

Thus, BC and AC intersect at (-42, -16)

Now, we solve eq. (iii) and (i)

$$x - 3y - 6 = 0 \dots(\text{iii})$$

$$3x + 2y + 6 = 0 \dots(\text{i})$$

Multiplying the eq. (iii) by 3, we get

$$3x - 9y - 18 = 0 \dots(\text{v})$$

Subtracting eq. (v) from (i), we get

$$3x + 2y + 6 - 3x + 9y + 18 = 0$$

$$\Rightarrow 11y + 24 = 0$$

$$\Rightarrow 11y = -24$$

$$\Rightarrow y = -\frac{24}{11}$$

Putting the value of y in eq. (iii), we get

$$x - 3\left(-\frac{24}{11}\right) - 6 = 0$$

$$\Rightarrow x + \frac{72}{11} - 6 = 0$$

$$\Rightarrow x = 6 - \frac{72}{11}$$

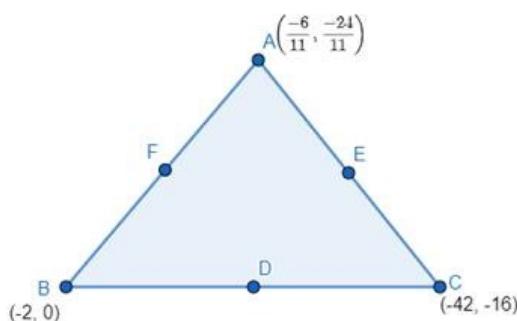

$$\Rightarrow x = \frac{66 - 72}{11}$$

$$\Rightarrow x = -\frac{6}{11}$$

Thus, AC and AB intersect at $\left(-\frac{6}{11}, -\frac{24}{11}\right)$

So, vertices of triangle ABC are : A $\left(-\frac{6}{11}, -\frac{24}{11}\right)$, B (-2, 0) & C (-42, -16)

Let D, E and F be the midpoints of sides BC, CA and AB respectively.

Then the coordinates of D, E and F are

$$\text{Coordinates of D} = \left(\frac{-42 + (-2)}{2}, \frac{-16 + 0}{2} \right)$$

$$= \left(\frac{-42 - 2}{2}, -\frac{16}{2} \right)$$

$$= \left(-\frac{44}{2}, -8 \right)$$

$$\text{Coordinates of E} = \left(\frac{-42 + \left(-\frac{6}{11}\right)}{2}, \frac{-16 + \left(-\frac{24}{11}\right)}{2} \right)$$

$$= \left(\frac{-42 - \frac{6}{11}}{2}, \frac{-16 - \frac{24}{11}}{2} \right)$$

$$= \left(\frac{-462 - 6}{22}, \frac{-176 - 24}{22} \right)$$

$$= \left(-\frac{468}{22}, -\frac{200}{22} \right)$$

$$= \left(-\frac{234}{11}, -\frac{100}{11} \right)$$

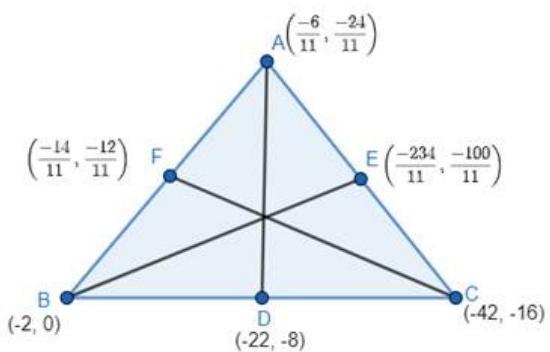

$$\text{Coordinates of F} = \left(\frac{-\frac{6}{11} + (-2)}{2}, \frac{-\frac{24}{11} + 0}{2} \right)$$

$$= \left(\frac{-6 - 22}{22}, -\frac{24}{22} \right)$$

$$= \left(-\frac{28}{22}, -\frac{12}{11} \right)$$

$$= \left(-\frac{14}{11}, -\frac{12}{11} \right)$$

Now, we have to find the equations of Medians AD, BE and CF

The equation of median AD is

$$y - \left(-\frac{24}{11} \right) = \frac{-8 - \left(-\frac{24}{11} \right)}{-22 - \left(-\frac{6}{11} \right)} \left[x - \left(-\frac{6}{11} \right) \right]$$

$$\Rightarrow y + \frac{24}{11} = \frac{\frac{-88 + 24}{11}}{\frac{-222 + 6}{11}} \left(x + \frac{6}{11} \right)$$

$$\Rightarrow y + \frac{24}{11} = \frac{-64}{-216} \left(x + \frac{6}{11} \right)$$

$$\Rightarrow y + \frac{24}{11} = \frac{16}{59} \left(x + \frac{6}{11} \right)$$

$$\Rightarrow y + \frac{24}{11} = \frac{16}{59}x + \frac{96}{59 \times 11}$$

$$\Rightarrow \frac{16}{59}x - y = \frac{24}{11} - \frac{96}{59 \times 11}$$

$$\Rightarrow \frac{16x - 59y}{59} = \frac{1416 - 96}{59 \times 11}$$

$$\Rightarrow 16x - 59y = \frac{1320}{11}$$

$$\Rightarrow 16x - 59y = 120$$

The equation of the median BE is

$$y - (0) = \frac{-\frac{100}{11} - 0}{-\frac{234}{11} - (-2)} \left[x - (-2) \right]$$

$$\Rightarrow y = \frac{-\frac{100}{11}}{\frac{-234 + 2}{11}} (x + 2)$$

$$\Rightarrow y = \frac{-100}{-232} (x + 2)$$

$$\Rightarrow y = \frac{25}{58}(x + 2)$$

$$\Rightarrow 58y = 25x + 50$$

$$\Rightarrow 25x - 58y + 50 = 0$$

The equation of median AD is

$$y - (-16) = \frac{-16 - \left(-\frac{12}{11}\right)}{-42 - \left(-\frac{14}{11}\right)} [x - (-42)]$$

$$\Rightarrow y + 16 = \frac{\frac{-176 + 12}{11}}{\frac{-462 + 14}{11}} (x + 42)$$

$$\Rightarrow y + 16 = \frac{-164}{-448} (x + 42)$$

$$\Rightarrow y + 16 = \frac{41}{112} (x + 42)$$

$$\Rightarrow 112y + 1792 = 41x + 1722$$

$$\Rightarrow 41x - 112y + 1722 - 1792 = 0$$

$$\Rightarrow 41x - 112y - 70 = 0$$

Exercise : 20J

Question: 1

If the origin is

Solution:

Let the new origin be $(h, k) = (1, 2)$ and $(x, y) = (3, -4)$ be the given point.

Let the new coordinates be (X, Y)

We use the transformation formula:

$$x = X + h \text{ and } y = Y + k$$

$$\Rightarrow 3 = X + 1 \text{ and } -4 = Y + 2$$

$$\Rightarrow X = 2 \text{ and } Y = -6$$

Thus, the new coordinates are $(2, -6)$

Question: 2

If the origin is

Solution:

Let the new origin be $(h, k) = (-3, -2)$ and $(x, y) = (3, -5)$ be the given point.

Let the new coordinates be (X, Y)

We use the transformation formula:

$$x = X + h \text{ and } y = Y + k$$

$$\Rightarrow 3 = X - 3 \text{ and } -5 = Y - 2$$

$\Rightarrow X = 6$ and $Y = -3$

Thus, the new coordinates are $(6, -3)$

Question: 3

If the origin is

Solution:

Let the new origin be $(h, k) = (0, -2)$ and $(x, y) = (3, 2)$ be the given point.

Let the new coordinates be (X, Y)

We use the transformation formula:

$$x = X + h \text{ and } y = Y + k$$

$$\Rightarrow 3 = X + 0 \text{ and } 2 = Y + (-2)$$

$$\Rightarrow X = 3 \text{ and } Y = 4$$

Thus, the new coordinates are $(3, 4)$

Question: 4

If the origin is

Solution:

Let the new origin be $(h, k) = (2, -1)$ and $(x, y) = (-3, 5)$ be the given point.

Let the new coordinates be (X, Y)

We use the transformation formula:

$$x = X + h \text{ and } y = Y + k$$

$$\Rightarrow -3 = X + 2 \text{ and } 5 = Y + (-1)$$

$$\Rightarrow X = -5 \text{ and } Y = 6$$

Thus, the new coordinates are $(-5, 6)$

Question: 5

At what point must

Solution:

Let (h, k) be the point to which the origin is shifted. Then,

$$x = -4, y = 2, X = 3 \text{ and } Y = -2$$

$$\therefore x = X + h \text{ and } y = Y + k$$

$$\Rightarrow -4 = 3 + h \text{ and } 2 = -2 + k$$

$$\Rightarrow h = -7 \text{ and } k = 4$$

Hence, the origin must be shifted to $(-7, 4)$

Question: 6

Find what the given

Solution:

Let the new origin be $(h, k) = (1, 1)$

Then, the transformation formula becomes:

$$x = X + 1 \text{ and } y = Y + 1$$

Substituting the value of x and y in the given equation, we get

$$x^2 + xy - 3x - y + 2 = 0$$

Thus,

$$\begin{aligned}(X+1)^2 + (X+1)(Y+1) - 3(X+1) - (Y+1) + 2 &= 0 \\ \Rightarrow (X^2 + 1 + 2X) + XY + X + Y + 1 - 3X - 3 - Y - 1 + 2 &= 0 \\ \Rightarrow X^2 + 1 + 2X + XY - 2X - 1 &= 0 \\ \Rightarrow X^2 + XY &= 0\end{aligned}$$

Hence, the transformed equation is $X^2 + XY = 0$

Question: 7

Find what the given

Solution:

Let the new origin be $(h, k) = (1, 1)$

Then, the transformation formula become:

$$x = X + 1 \text{ and } y = Y + 1$$

Substituting the value of x and y in the given equation, we get

$$xy - y^2 - x + y = 0$$

Thus,

$$\begin{aligned}(X+1)(Y+1) - (Y+1)^2 - (X+1) + (Y+1) &= 0 \\ \Rightarrow XY + X + Y + 1 - (Y^2 + 1 + 2Y) - X - 1 + Y + 1 &= 0 \\ \Rightarrow XY + X + Y + 1 - Y^2 - 1 - 2Y - X + Y &= 0 \\ \Rightarrow XY - Y^2 &= 0\end{aligned}$$

Hence, the transformed equation is $XY - Y^2 = 0$

Question: 8

Find what the given

Solution:

Let the new origin be $(h, k) = (1, 1)$

Then, the transformation formula become:

$$x = X + 1 \text{ and } y = Y + 1$$

Substituting the value of x and y in the given equation, we get

$$x^2 - y^2 - 2x + 2y = 0$$

Thus,

$$\begin{aligned}(X+1)^2 - (Y+1)^2 - 2(X+1) + 2(Y+1) &= 0 \\ \Rightarrow (X^2 + 1 + 2X) - (Y^2 + 1 + 2Y) - 2X - 2 + 2Y + 2 &= 0 \\ \Rightarrow X^2 + 1 + 2X - Y^2 - 1 - 2Y - 2X + 2Y &= 0 \\ \Rightarrow X^2 - Y^2 &= 0\end{aligned}$$

Hence, the transformed equation is $X^2 - Y^2 = 0$

Question: 9

Find what the given

Solution:

Let the new origin be $(h, k) = (1, 1)$

Then, the transformation formula become:

$$x = X + 1 \text{ and } y = Y + 1$$

Substituting the value of x and y in the given equation, we get

$$xy - x - y + 1 = 0$$

Thus,

$$(X + 1)(Y + 1) - (X + 1) - (Y + 1) + 1 = 0$$

$$\Rightarrow XY + X + Y + 1 - X - 1 - Y - 1 + 1 = 0$$

$$\Rightarrow XY = 0$$

Hence, the transformed equation is $XY = 0$

Question: 10

Transform the equ

Solution:

Let the new origin be $(h, k) = (1, -2)$

Then, the transformation formula become:

$$x = X + 1 \text{ and } y = Y + (-2) = Y - 2$$

Substituting the value of x and y in the given equation, we get

$$2x^2 + y^2 - 4x + 4y = 0$$

Thus,

$$2(X + 1)^2 + (Y - 2)^2 - 4(X + 1) + 4(Y - 2) = 0$$

$$\Rightarrow 2(X^2 + 1 + 2X) + (Y^2 + 4 - 4Y) - 4X - 4 + 4Y - 8 = 0$$

$$\Rightarrow 2X^2 + 2 + 4X + Y^2 + 4 - 4Y - 4X + 4Y - 12 = 0$$

$$\Rightarrow 2X^2 + Y^2 - 6 = 0$$

$$\Rightarrow 2X^2 + Y^2 = 6$$

Hence, the transformed equation is $2X^2 + Y^2 = 6$

Exercise : 20K

Question: 1

Find the equation

Solution:

Suppose the given two lines intersect at a point $P(x_1, y_1)$. Then, (x_1, y_1) satisfies each of the given equations.

$$x - 2y + 3 = 0 \dots(i)$$

$$2x - 3y + 4 = 0 \dots(ii)$$

Now, we find the point of intersection of eq. (i) and (ii)

Multiply the eq. (i) by 2, we get

$$2x - 4y + 6 = 0 \dots(iii)$$

On subtracting eq. (iii) from (ii), we get

$$2x - 3y + 4 - 2x + 4y - 6 = 0$$

$$\Rightarrow y - 2 = 0$$

$$\Rightarrow y = 2$$

Putting the value of y in eq. (i), we get

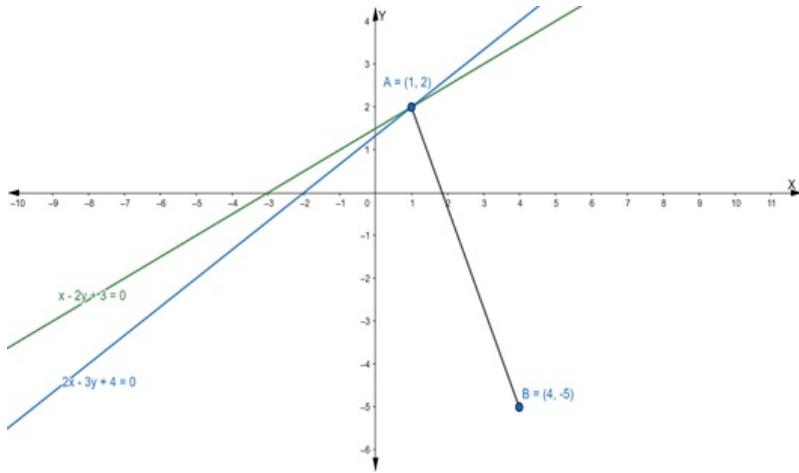

$$x - 2(2) + 3 = 0$$

$$\Rightarrow x - 4 + 3 = 0$$

$$\Rightarrow x - 1 = 0$$

$$\Rightarrow x = 1$$

Hence, the point of intersection P(x₁, y₁) is (1, 2)

Let AB is the line drawn from the point of intersection (1, 2) and passing through the point (4, -5)

Firstly, we find the slope of the line joining the points (1, 2) and (4, -5)

$$\text{Slope of line joining two points} = \frac{y_2 - y_1}{x_2 - x_1}$$

$$\therefore m_{AB} = \frac{-5 - 2}{4 - 1} = \frac{-7}{3}$$

Now, we have to find the equation of line passing through point (4, -5)

$$\text{Equation of line: } y - y_1 = m(x - x_1)$$

$$\Rightarrow y - (-5) = -\frac{7}{3}(x - 4)$$

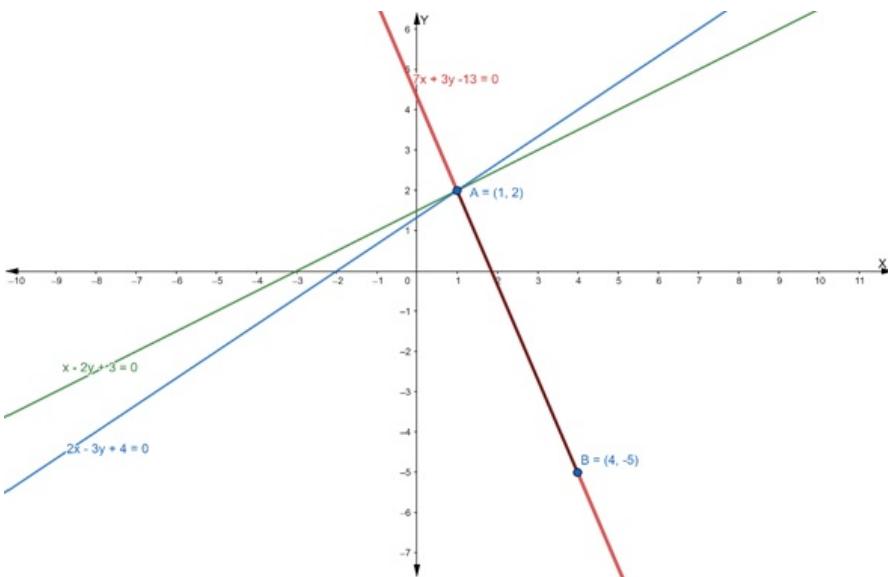

$$\Rightarrow y + 5 = -\frac{7}{3}(x - 4)$$

$$\Rightarrow 3y + 15 = -7x + 28$$

$$\Rightarrow 7x + 3y + 15 - 28 = 0$$

$$\Rightarrow 7x + 3y - 13 = 0$$

Hence, the equation of line passing through the point (4, -5) is $7x + 3y - 13 = 0$

Question: 2

Find the equation

Solution:

Suppose the given two lines intersect at a point $P(x_1, y_1)$. Then, (x_1, y_1) satisfies each of the given equations.

$$x - y = 7 \dots(i)$$

$$2x + y = 2 \dots(ii)$$

Now, we find the point of intersection of eq. (i) and (ii)

Multiply the eq. (i) by 2, we get

$$2x - 2y = 14 \dots(iii)$$

On subtracting eq. (iii) from (ii), we get

$$2x - 2y - 2x - y = 14 - 2$$

$$\Rightarrow -3y = 12$$

$$\Rightarrow y = -4$$

Putting the value of y in eq. (i), we get

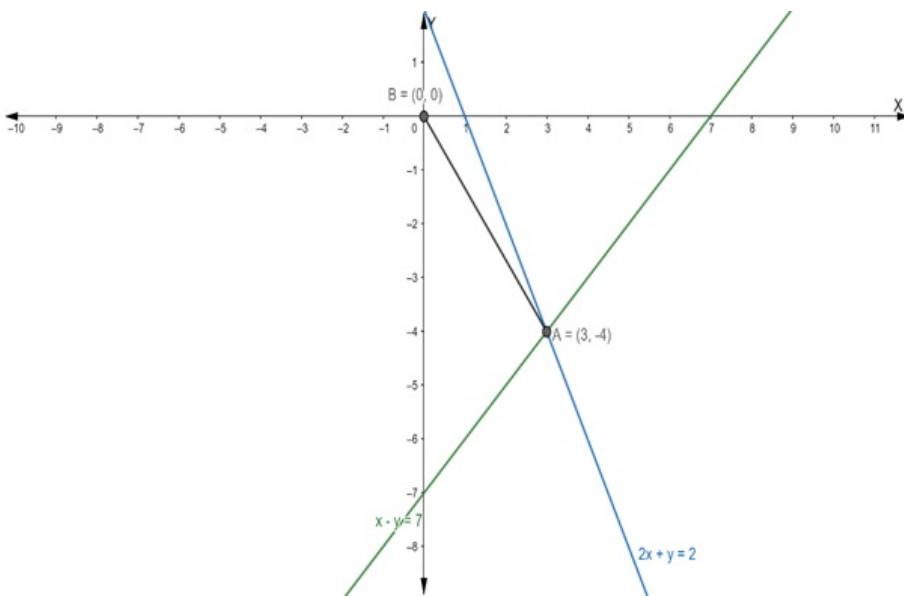

$$x - (-4) = 7$$

$$\Rightarrow x + 4 = 7$$

$$\Rightarrow x = 7 - 4$$

$$\Rightarrow x = 3$$

Hence, the point of intersection $P(x_1, y_1)$ is $(3, -4)$

Let AB is the line drawn from the point of intersection (3, -4) and passing through the origin.

Firstly, we find the slope of the line joining the points (3, -4) and (0, 0)

$$\text{Slope of line joining two points} = \frac{y_2 - y_1}{x_2 - x_1}$$

$$\therefore m_{AB} = \frac{0 - (-4)}{0 - 3} = \frac{4}{-3}$$

Now, we have to find the equation of the line passing through the origin

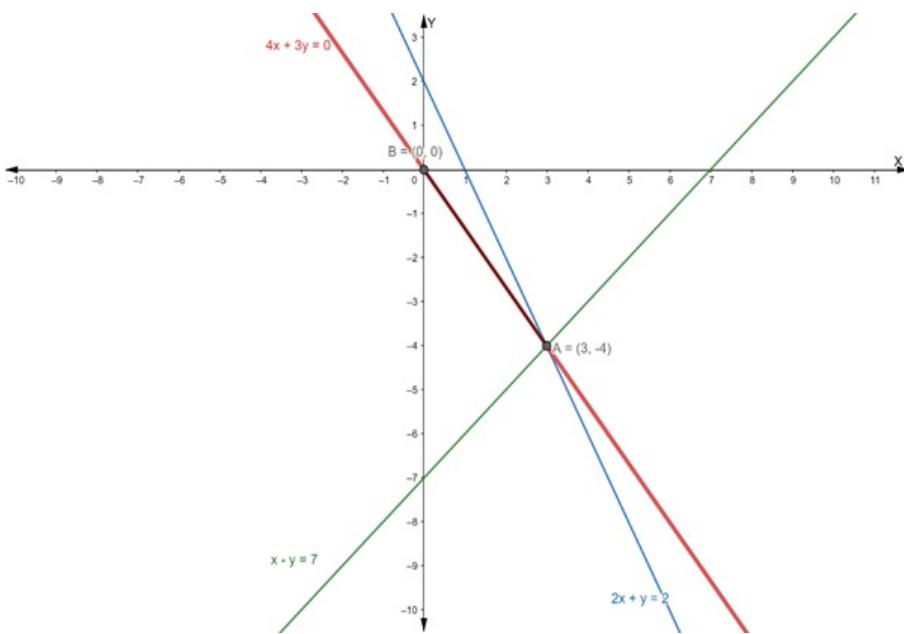

$$\text{Equation of line: } y - y_1 = m(x - x_1)$$

$$\Rightarrow y - 0 = -\frac{4}{3}(x - 0)$$

$$\Rightarrow 3y = -4x$$

$$\Rightarrow 4x + 3y = 0$$

Hence, the equation of the line passing through the origin is $4x + 3y = 0$

Question: 3

Find the equation

Solution:

Suppose the given two lines intersect at a point $P(x_1, y_1)$. Then, (x_1, y_1) satisfies each of the given equations.

$$x + y = 9 \dots(i)$$

$$2x - 3y + 7 = 0 \dots(ii)$$

Now, we find the point of intersection of eq. (i) and (ii)

Multiply the eq. (i) by 2, we get

$$2x + 2y = 18$$

$$\text{or } 2x + 2y - 18 = 0 \dots(iii)$$

On subtracting eq. (iii) from (ii), we get

$$2x - 3y + 7 - 2x - 2y + 18 = 0$$

$$\Rightarrow -5y + 25 = 0$$

$$\Rightarrow -5y = -25$$

$$\Rightarrow y = 5$$

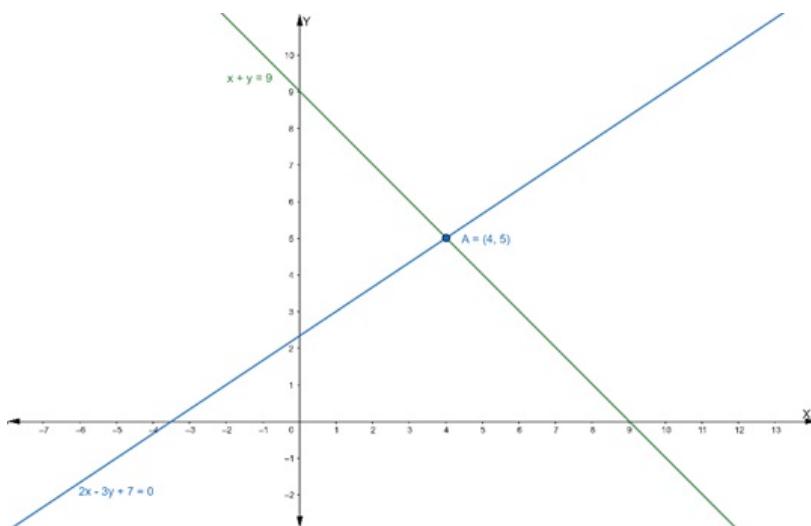

Putting the value of y in eq. (i), we get

$$x + 5 = 9$$

$$\Rightarrow x = 9 - 5$$

$$\Rightarrow x = 4$$

Hence, the point of intersection $P(x_1, y_1)$ is $(4, 5)$

Now, we have to find the equation of the line passing through the point $(4, 5)$ and having slope

$$= -\frac{2}{3}$$

Equation of line: $y - y_1 = m(x - x_1)$

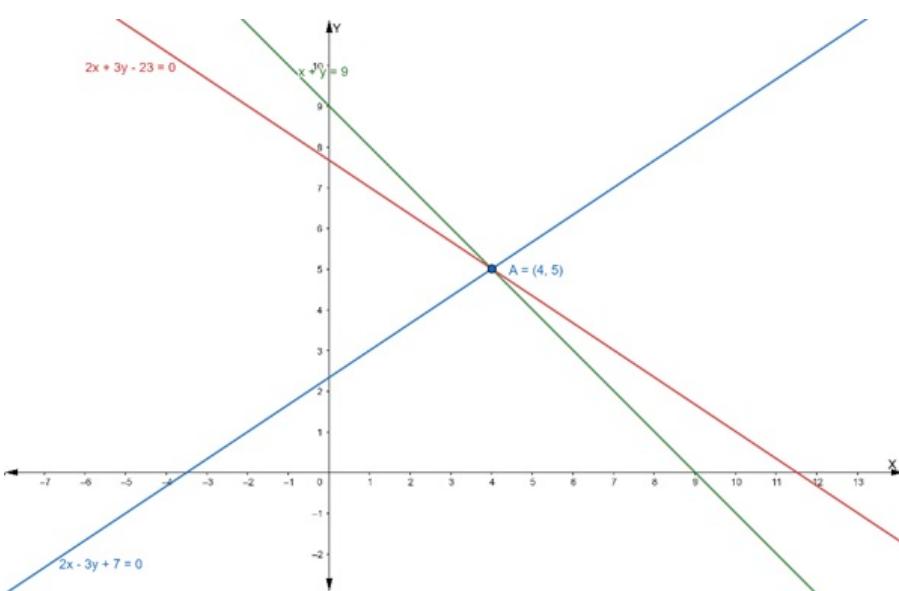

$$\Rightarrow y - 5 = -\frac{2}{3}(x - 4)$$

$$\Rightarrow 3y - 15 = -2x + 8$$

$$\Rightarrow 2x + 3y - 15 - 8 = 0$$

$$\Rightarrow 2x + 3y - 23 = 0$$

Hence, the equation of line having slope $-2/3$ is $2x + 3y - 23 = 0$

Question: 4

Find the equation

Solution:

Suppose the given two lines intersect at a point $P(x_1, y_1)$. Then, (x_1, y_1) satisfies each of the given equations.

$$x - y = 1 \dots(i)$$

$$2x - 3y + 1 = 0 \dots(ii)$$

Now, we find the point of intersection of eq. (i) and (ii)

Multiply the eq. (i) by 2, we get

$$2x - 2y = 2$$

$$\text{or } 2x - 2y - 2 = 0 \dots(iii)$$

On subtracting eq. (iii) from (ii), we get

$$2x - 3y + 1 - 2x + 2y + 2 = 0$$

$$\Rightarrow -y + 3 = 0$$

$$\Rightarrow y = 3$$

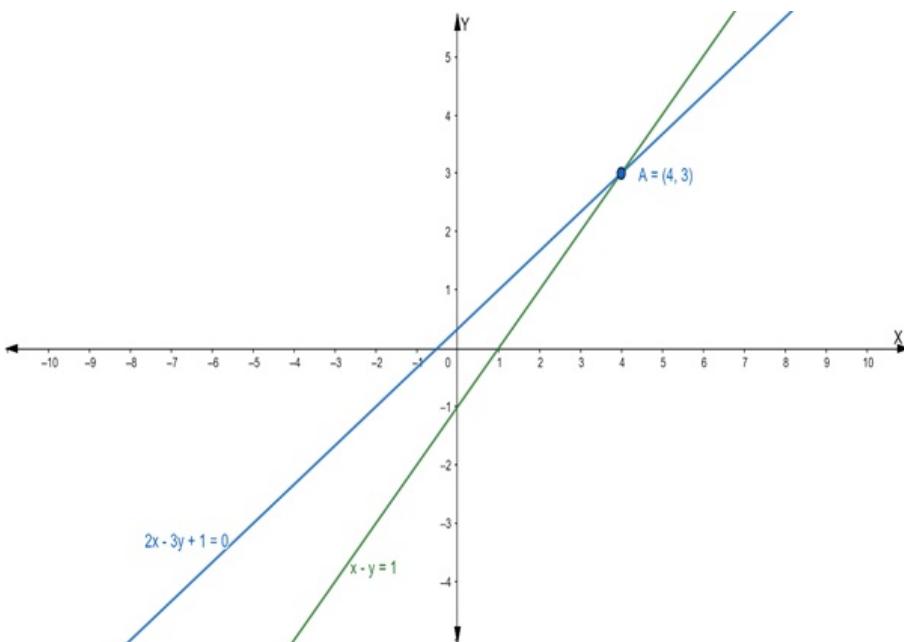

Putting the value of y in eq. (i), we get

$$x - 3 = 1$$

$$\Rightarrow x = 1 + 3$$

$$\Rightarrow x = 4$$

Hence, the point of intersection $P(x_1, y_1)$ is $(4, 3)$

Now, we find the slope of the given equation $3x + 4y = 12$

We know that the slope of an equation is

$$m = -\frac{a}{b}$$

$$\Rightarrow m = -\frac{3}{4}$$

So, the slope of a line which is parallel to this line is also $-\frac{3}{4}$

Then the equation of the line passing through the point $(4, 3)$ having a slope $-\frac{3}{4}$ is:

$$y - y_1 = m(x - x_1)$$

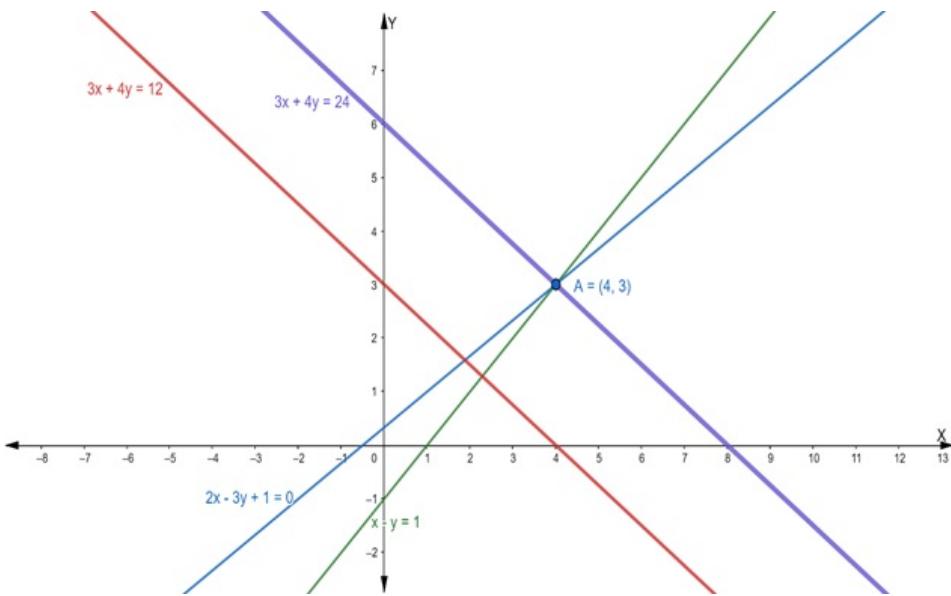

$$\Rightarrow y - 3 = -\frac{3}{4}(x - 4)$$

$$\Rightarrow y - 3 = -3x + 12$$

$$\Rightarrow 4y - 12 = -3x + 12$$

$$\Rightarrow 3x + 4y - 12 - 12 = 0$$

$$\Rightarrow 3x + 4y - 24 = 0$$

Question: 5

Find the equation

Solution:

Suppose the given two lines intersect at a point $P(x_1, y_1)$. Then, (x_1, y_1) satisfies each of the given equations.

$$5x - 3y = 1 \dots(i)$$

$$2x + 3y = 23 \dots(ii)$$

Now, we find the point of intersection of eq. (i) and (ii)

Adding eq. (i) and (ii) we get

$$5x - 3y + 2x + 3y = 1 + 23$$

$$\Rightarrow 7x = 24$$

$$\Rightarrow x = \frac{24}{7}$$

Putting the value of x in eq. (i), we get

$$5\left(\frac{24}{7}\right) - 3y = 1$$

$$\Rightarrow \frac{120}{7} - 3y = 1$$

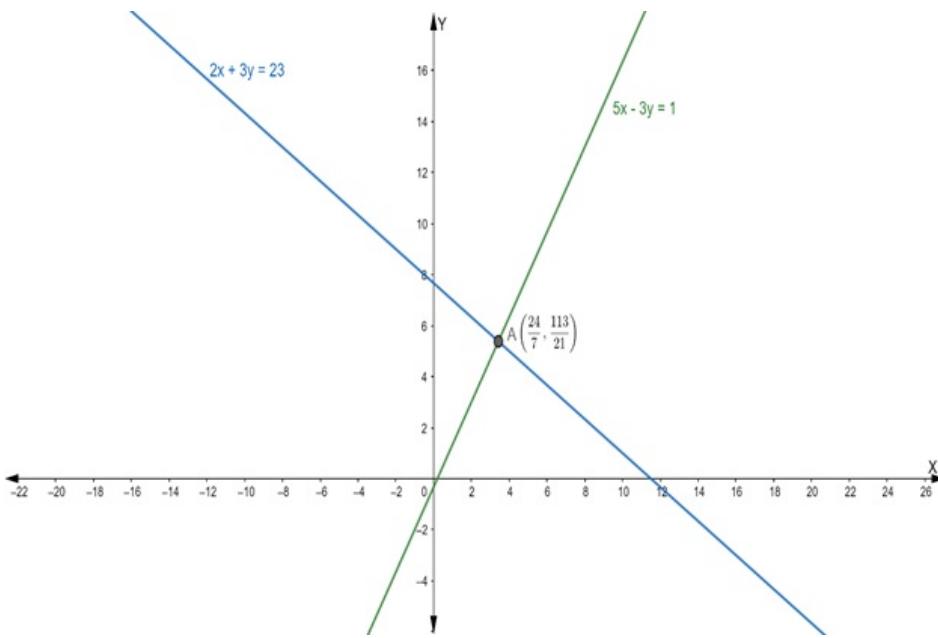

$$\Rightarrow -3y = 1 - \frac{120}{7}$$

$$\Rightarrow -3y = \frac{7 - 120}{7}$$

$$\Rightarrow -3y = -\frac{113}{7}$$

$$\Rightarrow y = \frac{113}{21}$$

Hence, the point of intersection $P(x_1, y_1)$ is $\left(\frac{24}{7}, \frac{113}{21}\right)$

Now, we know that, when two lines are perpendicular, then the product of their slope is equal to -1

$$m_1 \times m_2 = -1$$

$$\Rightarrow \text{Slope of the given line} \times \text{Slope of the perpendicular line} = -1$$

$$\therefore \frac{5}{3} \times \text{Slope of the perpendicular line} = -1$$

$$\Rightarrow \text{The slope of the perpendicular line} = -\frac{3}{5}$$

So, the slope of a line which is perpendicular to the given line is $-\frac{3}{5}$

Then the equation of the line passing through the point $\left(\frac{24}{7}, \frac{113}{21}\right)$ having slope $-\frac{3}{5}$ is :

$$y - y_1 = m(x - x_1)$$

$$\Rightarrow y - \left(\frac{113}{21}\right) = -\frac{3}{5} \left(x - \frac{24}{7}\right)$$

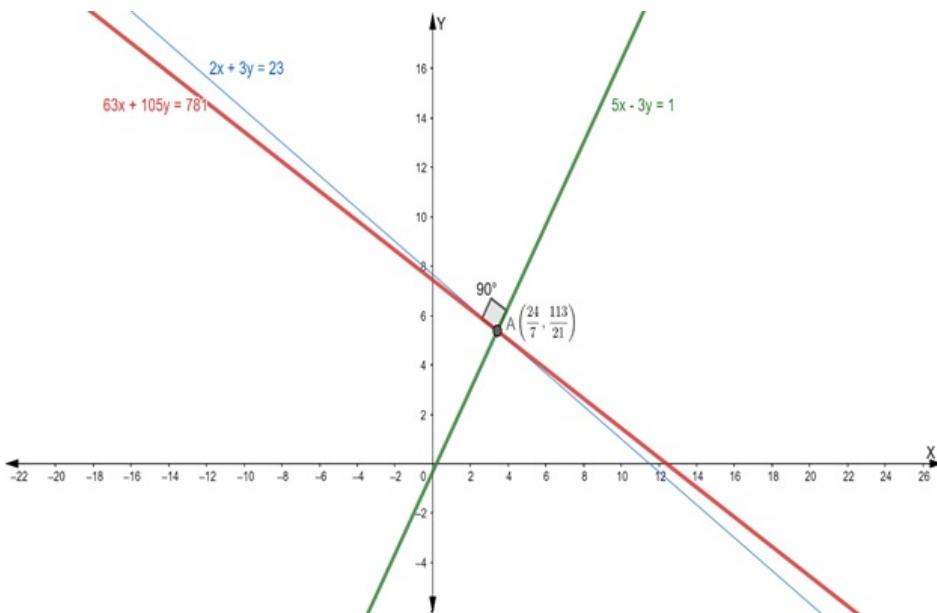

$$\Rightarrow 5y - 5 \times \frac{113}{21} = -3x + \frac{24}{7}$$

$$\Rightarrow 5y - \frac{565}{21} = -3x + \frac{72}{7}$$

$$\Rightarrow 3x + 5y - \frac{565}{21} - \frac{72}{7} = 0$$

$$\Rightarrow \frac{63x + 105y - 565 - 216}{21} = 0$$

$$\Rightarrow 63x + 105y - 781 = 0$$

Question: 6

Find the equation

Solution:

Suppose the given two lines intersect at a point $P(x_1, y_1)$. Then, (x_1, y_1) satisfies each of the given equations.

$$2x - 3y = 0 \dots \text{(i)}$$

$$4x - 5y = 2 \dots \text{(ii)}$$

Now, we find the point of intersection of eq. (i) and (ii)

Multiply the eq. (i) by 2, we get

$$4x - 6y = 0 \dots \text{(iii)}$$

On subtracting eq. (iii) from (ii), we get

$$4x - 5y - 4x + 6y = 2 - 0$$

$$\Rightarrow y = 2$$

Putting the value of y in eq. (i), we get

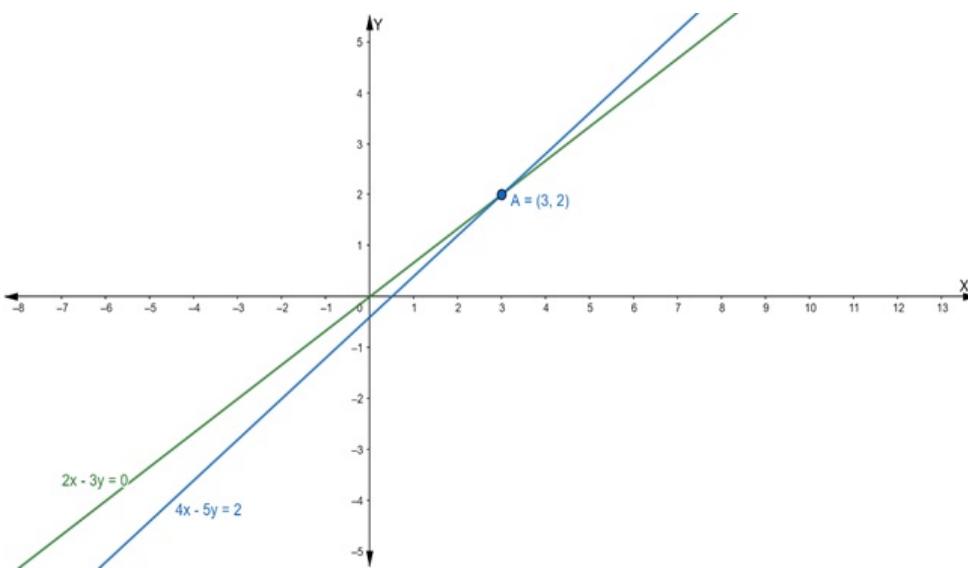

$$2x - 3(2) = 0$$

$$\Rightarrow 2x - 6 = 0$$

$$\Rightarrow 2x = 6$$

$$\Rightarrow x = 3$$

Hence, the point of intersection $P(x_1, y_1)$ is $(3, 2)$

Now, we know that, when two lines are perpendicular, then the product of their slope is equal to -1

$$m_1 \times m_2 = -1$$

$$\Rightarrow \text{Slope of the given line} \times \text{Slope of the perpendicular line} = -1$$

$$\therefore \left(-\frac{1}{2}\right) \times \text{Slope of the perpendicular line} = -1$$

$$\Rightarrow \text{The slope of the perpendicular line} = 2$$

So, the slope of a line which is perpendicular to the given line is 2

Then the equation of the line passing through the point (3, 2) having slope 2 is:

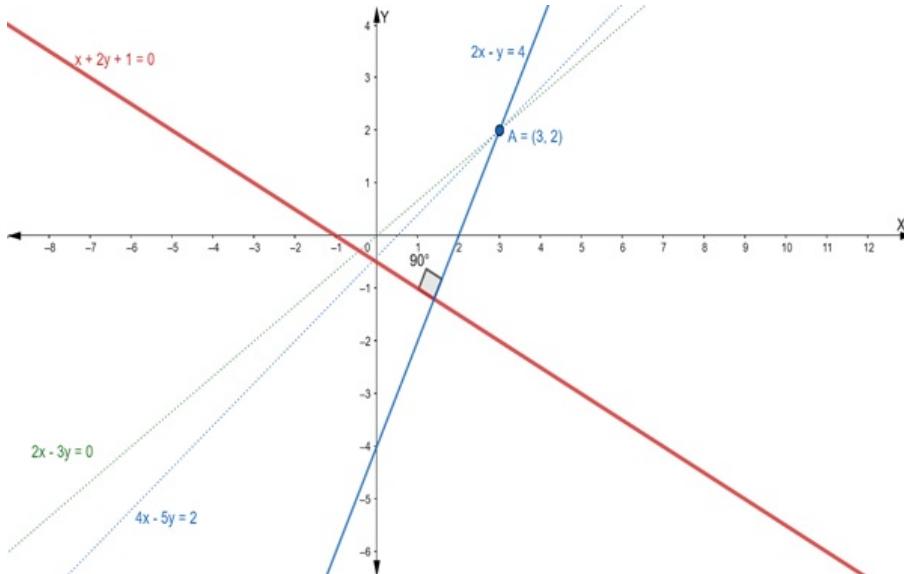

$$y - y_1 = m(x - x_1)$$

$$\Rightarrow y - 2 = 2(x - 3)$$

$$\Rightarrow y - 2 = 2x - 6$$

$$\Rightarrow 2x - y - 6 + 2 = 0$$

$$\Rightarrow 2x - y - 4 = 0$$

Question: 7

Find the equation

Solution:

Suppose the given two lines intersect at a point $P(x_1, y_1)$. Then, (x_1, y_1) satisfies each of the given equations.

$$x - 7y + 5 = 0 \dots(i)$$

$$3x + y - 7 = 0 \dots(ii)$$

Now, we find the point of intersection of eq. (i) and (ii)

Multiply the eq. (i) by 3, we get

$$3x - 21y + 15 = 0 \dots(iii)$$

On subtracting eq. (iii) from (ii), we get

$$3x + y - 7 - 3x + 21y - 15 = 0$$

$$\Rightarrow 22y - 22 = 0$$

$$\Rightarrow 22y = 22$$

$$\Rightarrow y = 1$$

Putting the value of y in eq. (i), we get

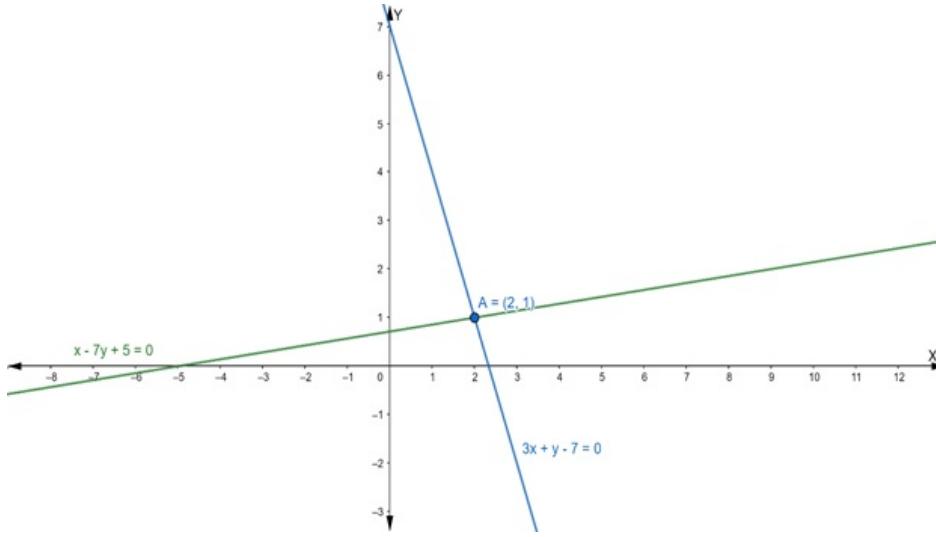

$$x - 7(1) + 5 = 0$$

$$\Rightarrow x - 7 + 5 = 0$$

$$\Rightarrow x - 2 = 0$$

$$\Rightarrow x = 2$$

Hence, the point of intersection $P(x_1, y_1)$ is $(2, 1)$

The equation of line parallel to x -axis is of the form

$$y = b \text{ where } b \text{ is some constant}$$

Given that this equation of the line passing through the point of intersection $(2, 1)$

Hence, point $(2, 1)$ will satisfy the equation of a line.

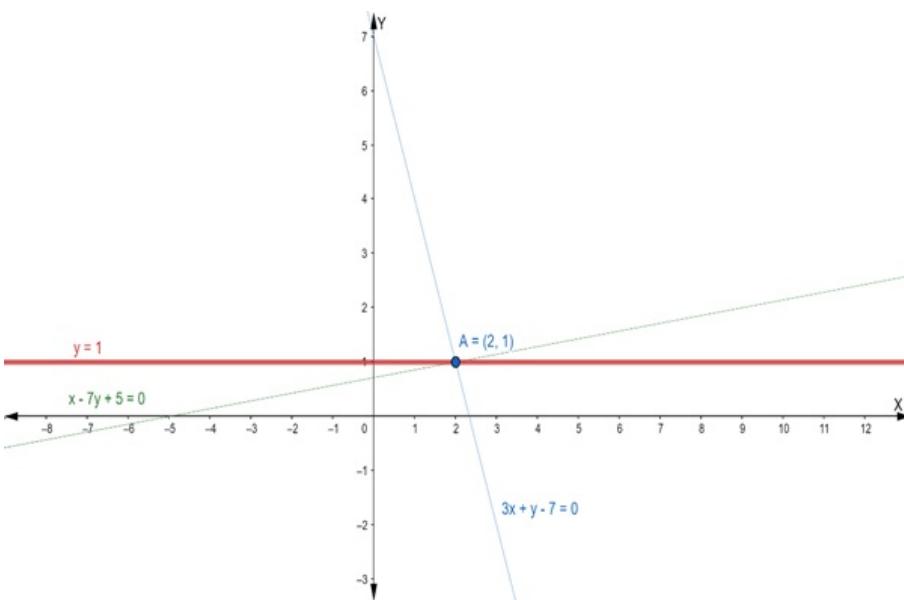

Putting $y = 1$ in the equation $y = b$, we get

$$y = b$$

$$\Rightarrow 1 = b$$

$$\text{or } b = 1$$

Now, the required equation of a line is $y = 1$

Question: 8

Find the equation

Solution:

Suppose the given two lines intersect at a point $P(x_1, y_1)$. Then, (x_1, y_1) satisfies each of the given equations.

$$2x - 3y + 1 = 0 \dots(i)$$

$$x + y - 2 = 0 \dots(ii)$$

Now, we find the point of intersection of eq. (i) and (ii)

Multiply the eq. (ii) by 2, we get

$$2x + 2y - 4 = 0 \dots(iii)$$

On subtracting eq. (iii) from (i), we get

$$2x - 3y + 1 - 2x - 2y + 4 = 0$$

$$\Rightarrow -5y + 5 = 0$$

$$\Rightarrow -5y = -5$$

$$\Rightarrow y = 1$$

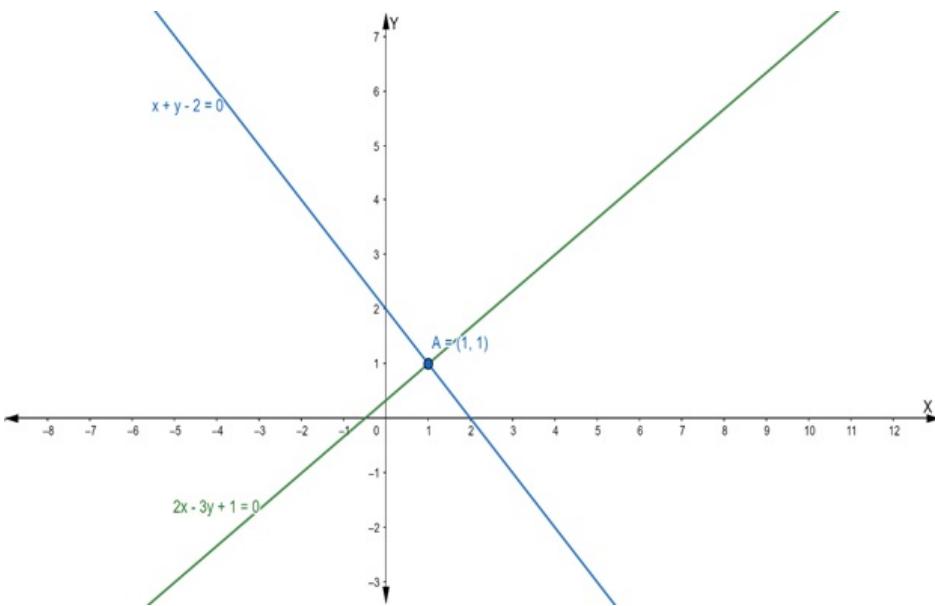

Putting the value of y in eq. (ii), we get

$$x + 1 - 2 = 0$$

$$\Rightarrow x - 1 = 0$$

$$\Rightarrow x = 1$$

Hence, the point of intersection $P(x_1, y_1)$ is $(1, 1)$

The equation of a line parallel to y -axis is of the form

$$x = a \text{ where } a \text{ is some constant}$$

Given that this equation of the line passing through the point of intersection (1, 1)

Hence, point (1, 1) will satisfy the equation of a line.

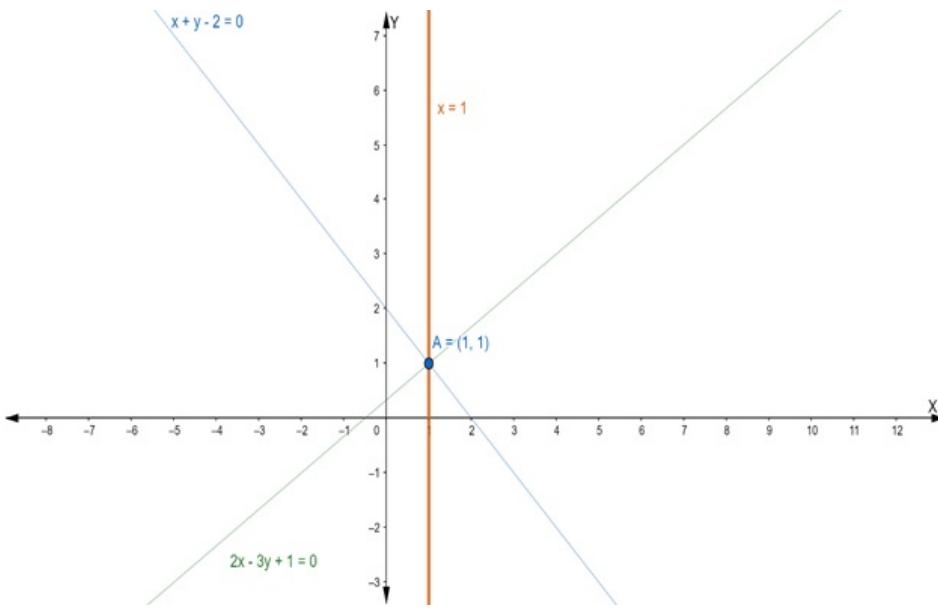

Putting $x = 1$ in the equation $y = b$, we get

$$x = a$$

$$\Rightarrow 1 = a$$

$$\text{or } a = 1$$

Now, required equation of line is $x = 1$

Question: 9

Find the equation

Solution:

Suppose the given two lines intersect at a point $P(x_1, y_1)$. Then, (x_1, y_1) satisfies each of the given equations.

$$2x + 3y - 2 = 0 \dots(i)$$

$$x - 2y + 1 = 0 \dots(ii)$$

Now, we find the point of intersection of eq. (i) and (ii)

Multiply the eq. (ii) by 2, we get

$$2x - 4y + 2 = 0 \dots(\text{iii})$$

On subtracting eq. (iii) from (i), we get

$$2x + 3y - 2 - 2x + 4y - 2 = 0$$

$$\Rightarrow 7y - 4 = 0$$

$$\Rightarrow 7y = 4$$

$$\Rightarrow y = \frac{4}{7}$$

Putting the value of y in eq. (ii), we get

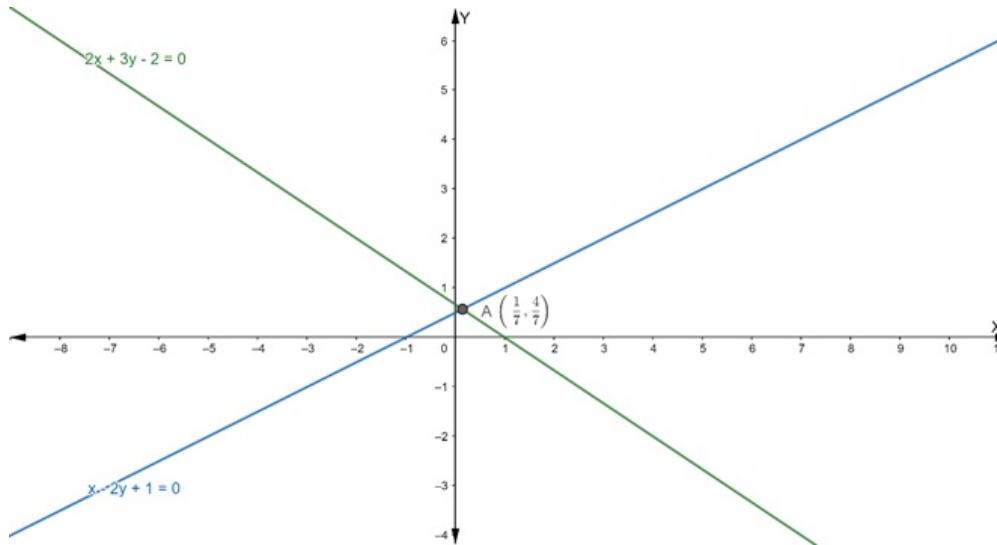

$$x - 2\left(\frac{4}{7}\right) + 1 = 0$$

$$\Rightarrow x - \frac{8}{7} + 1 = 0$$

$$\Rightarrow x = \frac{8}{7} - 1$$

$$\Rightarrow x = \frac{1}{7}$$

Hence, the point of intersection P(x₁, y₁) is $\left(\frac{1}{7}, \frac{4}{7}\right)$

Now, the equation of a line in intercept form is:

$$\frac{x}{a} + \frac{y}{b} = 1$$

where a and b are the intercepts on the axis.

Given that: a = 3

$$\Rightarrow \frac{x}{3} + \frac{y}{b} = 1$$

$$\Rightarrow \frac{bx + 3y}{3b} = 1$$

$$\Rightarrow bx + 3y = 3b \dots(i)$$

If eq. (i) passes through the point $\left(\frac{1}{7}, \frac{4}{7}\right)$, we get

$$b\left(\frac{1}{7}\right) + 3\left(\frac{4}{7}\right) = 3b$$

$$\Rightarrow \frac{b+12}{7} = 3b$$

$$\Rightarrow b + 12 = 21b$$

$$\Rightarrow b - 21b = -12$$

$$\Rightarrow 20b = 12$$

$$\Rightarrow b = \frac{12}{20} = \frac{3}{5}$$

Putting the value of 'b' in eq. (i), we get

$$\frac{3}{5}x + 3y = 3 \times \frac{3}{5}$$

$$\Rightarrow \frac{3}{5}x + 3y = \frac{9}{5}$$

$$\Rightarrow 3x + 15y = 9$$

$$\Rightarrow x + 5y = 3$$

Hence, the required equation of line is $x + 5y = 3$

Question: 10

Find the equation

Solution:

Suppose the given two lines intersect at a point $P(x_1, y_1)$. Then, (x_1, y_1) satisfies each of the given equations.

$$3x - 4y + 1 = 0 \dots(i)$$

$$5x + y - 1 = 0 \dots(ii)$$

Now, we find the point of intersection of eq. (i) and (ii)

Multiply the eq. (ii) by 4, we get

$$20x + 4y - 4 = 0 \dots(iii)$$

On adding eq. (iii) and (i), we get

$$20x + 4y - 4 + 3x - 4y + 1 = 0$$

$$\Rightarrow 23x - 3 = 0$$

$$\Rightarrow 23x = 3$$

$$\Rightarrow x = \frac{3}{23}$$

Putting the value of x in eq. (ii), we get

$$5\left(\frac{3}{23}\right) + y - 1 = 0$$

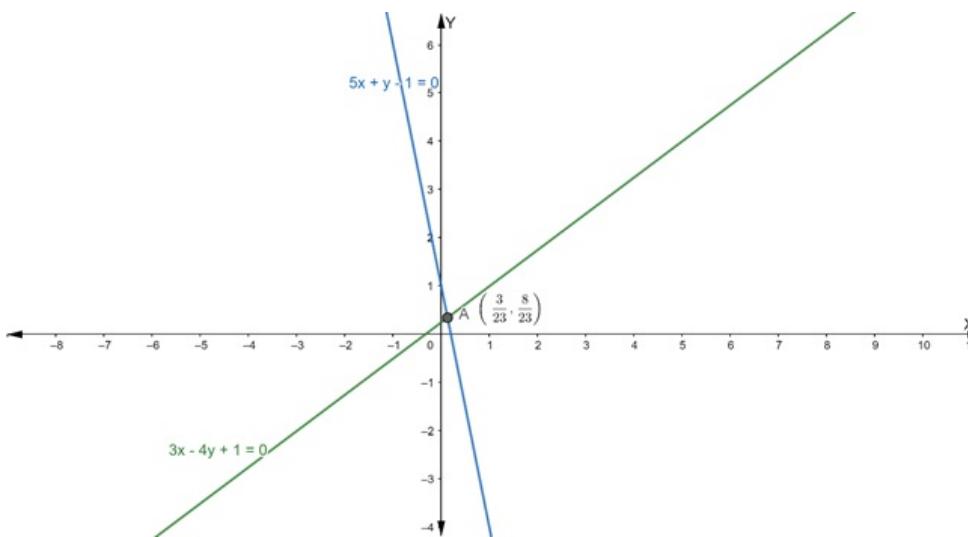

$$\Rightarrow \frac{15}{23} + y - 1 = 0$$

$$\Rightarrow y = 1 - \frac{15}{23}$$

$$\Rightarrow y = \frac{23 - 15}{23}$$

$$\Rightarrow y = \frac{8}{23}$$

Hence, the point of intersection P(x₁, y₁) is $\left(\frac{3}{23}, \frac{8}{23}\right)$

Now, the equation of line in intercept form is:

$$\frac{x}{a} + \frac{y}{b} = 1$$

where a and b are the intercepts on the axis.

Given that: a = b

$$\Rightarrow \frac{x}{a} + \frac{y}{a} = 1$$

$$\Rightarrow \frac{x + y}{a} = 1$$

$$\Rightarrow x + y = a \dots (i)$$

If eq. (i) passes through the point $\left(\frac{3}{23}, \frac{8}{23}\right)$, we get

$$\frac{3}{23} + \frac{8}{23} = a$$

$$\Rightarrow \frac{11}{23} = a$$

$$\Rightarrow a = \frac{11}{23}$$

Putting the value of 'a' in eq. (i), we get

$$x + y = \frac{11}{23}$$

$$\Rightarrow 23x + 23y = 11$$

Hence, the required line is $23x + 23y = 11$
